Agilent X-Series
Signal Analyzer

This manual provides documentation for the following X-Series Analyzers:

- PXA Signal Analyzer N9030A
- MXA Signal Analyzer N9020A
- EXA Signal Analyzer N9010A
- CXA Signal Analyzer N9000A

Warranty

The material contained in this document is provided “as is,” and is subject to being changed, without notice, in future editions. Further, to the maximum extent permitted by applicable law, Agilent disclaims all warranties, either express or implied, with regard to this manual and any information contained herein, including but not limited to the implied warranties of merchantability and fitness for a particular purpose. Agilent shall not be liable for errors or for incidental or consequential damages in connection with the furnishing, use, or performance of this document or of any information contained herein. Should Agilent and the user have a separate written agreement with warranty terms covering the material in this document that conflict with these terms, the warranty terms in the separate agreement shall control.

Technology Licenses

The hardware and/or software described in this document are furnished under a license and may be used or copied only in accordance with the terms of such license.

Restricted Rights Legend

If software is for use in the performance of a U.S. Government prime contract or subcontract, Software is delivered and licensed as “Commercial computer software” as defined in DFAR 252.227-7014 (June 1995), or as a “commercial item” as defined in FAR 2.101(a) or as “Restricted computer software” as defined in FAR 52.227-19 (June 1987) or any equivalent agency regulation or contract clause. Use, duplication or disclosure of Software is subject to Agilent Technologies’ standard commercial license terms, and non-DOD Departments and Agencies of the U.S. Government will receive no greater than Restricted Rights as defined in FAR 52.227-19(e)(1-2) (June 1987). U.S. Government users will receive no greater than Limited Rights as defined in FAR 52.227-14 (June 1987) or DFAR 252.227-7015(b)(2) (November 1995), as applicable in any technical data.

Safety Notices

CAUTION

A CAUTION notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in damage to the product or loss of important data. Do not proceed beyond a CAUTION notice until the indicated conditions are fully understood and met.

WARNING

A WARNING notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in personal injury or death. Do not proceed beyond a WARNING notice until the indicated conditions are fully understood and met.
Warranty

This Agilent technologies instrument product is warranted against defects in material and workmanship for a period of one year from the date of shipment. During the warranty period, Agilent Technologies will, at its option, either repair or replace products that prove to be defective.

For warranty service or repair, this product must be returned to a service facility designated by Agilent Technologies. Buyer shall prepay shipping charges to Agilent Technologies and Agilent Technologies shall pay shipping charges to return the product to Buyer. However, Buyer shall pay all shipping charges, duties, and taxes for products returned to Agilent Technologies from another country.

Where to Find the Latest Information

Documentation is updated periodically. For the latest information about this analyzer, including firmware upgrades, application information, and product information, see the following URLs:

1 Getting Started with the Spectrum Analyzer Measurement Application

This chapter provides some basic information about using the Spectrum Analyzer and IQ Analyzer Measurement Application Modes. It includes topics on:

- “Making a Basic Measurement” on page 10
- “Recommended Test Equipment” on page 15
- “Accessories Available” on page 16

Technical Documentation Summary:

<table>

Measurement Application specific documentation:
(for example, Spectrum Analyzer Measurement Application or W-CDMA Measurement Application)

| Measurement Guide                        | Examples of measurements made using the front panel keys or over a remote interface. |
| User’s/Programmer’s Reference            | Descriptions of front panel key functionality and the corresponding SCPI commands. May also include some concept information. |
Making a Basic Measurement

Refer to the description of the instrument front and rear panels to improve your understanding of the Agilent Signal Analyzer measurement platform. This knowledge will help you with the following measurement example.

This section includes:
- “Using the Front Panel” on page 10
- “Presetting the Signal Analyzer” on page 11
- “Viewing a Signal” on page 12

CAUTION
Make sure that the total power of all signals at the analyzer input does not exceed +30 dBm (1 watt).

Using the Front Panel

Entering Data

When setting measurement parameters, there are several ways to enter or modify the value of the active function:

- Knob: Increments or decrements the current value.
- Arrow Keys: Increments or decrements the current value.
- Numeric Keypad: Enters a specific value. Then press the desired terminator (either a unit softkey, or the Enter key).
- Unit Softkeys: Terminates a value that requires a unit-of-measurement.
- Enter Key: Terminates an entry when either no unit of measure is needed, or you want to use the default unit.

Using Menu Keys

Menu Keys (which appear along the right side of the display) provide access to many analyzer functions. Here are examples of menu key types:

- Toggle: Allows you to activate/deactivate states.
  Example: Toggles the selection (underlined choice) each time you press the key.

- Submenu: Displays a new menu of softkeys.
Getting Started with the Spectrum Analyzer Measurement Application

Making a Basic Measurement

Example:

A submenu key allows you to view a new menu of softkeys related to the submenu key category.

Choice

Allows you to make a selection from a list of values.

Example:

A choice key displays the currently selected submenu choice, in this example, dBm. When the choice is made, the submenu automatically returns.

Adjust

Highlights the softkey and sets the active function.

Examples:

The default for softkeys with an automatic (Auto) or manual (Man) choice is automatic. After you enter a value, the selection changes to manual. You can also press the softkey twice to change to manual.

Presetting the Signal Analyzer

The preset function provides a known starting point for making measurements. The analyzer has two main types of preset:

User Preset

Restores the analyzer to a user-defined state.

Mode Preset

This type of preset restores the currently selected mode to a default state.

For details, see the help or User’s and Programmer’s Reference.

Creating a User Preset

If you constantly use settings which are not the normal defaults, use the following steps to create a user-defined preset:

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set analyzer parameters as desired</td>
</tr>
</tbody>
</table>
| 2    | Set the current parameters as the user preset state  
  a. Press User Preset, Save User Preset |
| 3    | To select a preset state  
  a. Press User Preset, User Preset |
Getting Started with the Spectrum Analyzer Measurement Application

Making a Basic Measurement

Viewing a Signal

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Return the current mode settings to factory defaults.</td>
<td>a. Press <strong>Mode Preset</strong>.</td>
</tr>
<tr>
<td>2</td>
<td>Route the internal 50 MHz signal to the analyzer input.</td>
<td>a. Press <strong>Input/Output, RF Calibrator, 50 MHz</strong>.</td>
</tr>
<tr>
<td>3</td>
<td>Set the reference level to 10 dBm.</td>
<td>a. Press <strong>AMPTD Y Scale, 10, dBm</strong>.</td>
</tr>
<tr>
<td>4</td>
<td>Set the center frequency to 40 MHz.</td>
<td>a. Press <strong>FREQ Channel, Center Freq, 40, MHz</strong>. The 50 MHz reference signal appears on the display.</td>
</tr>
<tr>
<td>5</td>
<td>Set the frequency span to 50 MHz.</td>
<td>a. Press <strong>SPAN, 50, MHz</strong>.</td>
</tr>
</tbody>
</table>

Reading Frequency & Amplitude

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Activate a marker and place it on the highest amplitude signal.</td>
<td>a. Press <strong>Peak Search</strong>. The frequency and amplitude of the marker appear in the active function block in the upper-right of the display. You can use the knob, the arrow keys, or the softkeys in the Peak Search menu to move the marker around on the signal.</td>
</tr>
<tr>
<td>2</td>
<td>To return the marker to the peak of the signal.</td>
<td>a. Press <strong>Peak Search</strong>.</td>
</tr>
</tbody>
</table>

Changing Reference Level

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Change the reference level.</td>
<td>a. Press <strong>AMPLTD Y Scale</strong>. The reference level is now the active function. &lt;br&gt;b. Press <strong>Marker -&gt;, Mkr -&gt; Ref Lvl</strong>.</td>
</tr>
</tbody>
</table>
### Improving Frequency Accuracy

**NOTE** When you use the frequency count function, if the ratio of the resolution bandwidth to the span is less than 0.002, you will get a display message that you need to reduce the Span/RBW ratio. This is because the resolution bandwidth is too narrow.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Activate the Marker Count menu.</td>
<td>a. Press Marker, More 1 of 2, Marker Count.</td>
</tr>
<tr>
<td>2</td>
<td>To increase the accuracy of the frequency reading in the marker annotation.</td>
<td>a. Press Counter. The marker active function annotation changes from Mkr1 to Cntr1. The displayed resolution in the marker annotation improves.</td>
</tr>
<tr>
<td>3</td>
<td>Move the signal peak to the center of the display.</td>
<td>a. Press Marker -&gt;, Mkr -&gt; CF.</td>
</tr>
</tbody>
</table>

### Valid Marker Count Range

**NOTE** Marker count functions properly only on CW signals or discrete peaks. For a valid reading, the marker must be \( \geq 26 \) dB above the noise.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Move the marker down the skirt of the 50 MHz peak.</td>
<td>Although the readout in the active function changes, as long as the marker is at least 26 dB above the noise, the counted value (upper-right corner of display) does not change. For an accurate count, the marker does not have to be exactly at the displayed peak</td>
</tr>
</tbody>
</table>

---

13
### Making a Basic Measurement

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 2    | Enter a new value.  
   a. Press **BW, Res BW** and enter a value. | This action makes the resolution bandwidth (RBW) the active function and allows you to experiment with different resolution bandwidth values. |
| 3    | Turn off the marker.  
   a. Press **Marker, Off**. | |
## Recommended Test Equipment

The following table lists the test equipment you will need to perform the example measurements described in this manual.

### NOTE
To find descriptions of specific analyzer functions for the N9060A Spectrum Analyzer Measurement Application, refer to the *Agilent Technologies X-Series User’s and Programmer’s Reference*.

Accessories Available

A number of accessories are available from Agilent Technologies to help you configure your analyzer for your specific applications. They can be ordered through your local Agilent Sales and Service Office and are listed below.

NOTE

There are also some instrument options available that can improve your measurements. Some options can only be ordered when you make your original equipment purchase. But some are also available as kits that you can order and install later. Order kits through your local Agilent Sales and Service Office.

For the latest information on Agilent signal analyzer options and upgrade kits, visit the following Internet URL: http://www.agilent.com/find/sa_upgrades

50 Ohm Load

The Agilent 909 series of loads come in several models and options providing a variety of frequency ranges and VSWRs. Also, they are available in either 50 ohm or 75 Ohm. Some examples include the:

- 909A: DC to 18 GHz
- 909C: DC to 2 GHz
- 909D: DC to 26.5 GHz

50 Ohm/75 Ohm Minimum Loss Pad

The HP/Agilent 11852B is a low VSWR minimum loss pad that allows you to make measurements on 75 Ohm devices using an analyzer with a 50 Ohm input. It is effective over a frequency range of dc to 2 GHz.

75 Ohm Matching Transformer

The HP/Agilent 11694A allows you to make measurements in 75 Ohm systems using an analyzer with a 50 Ohm input. It is effective over a frequency range of 3 to 500 MHz.

AC Probe

The Agilent 85024A high frequency probe performs in-circuit measurements without adversely loading the circuit under test. The probe has an input capacitance of 0.7 pF shunted by 1 megohm of resistance and operates over a frequency range of 300 kHz to 3 GHz. High probe sensitivity and low distortion levels allow measurements to be made while taking advantage of the full dynamic range of the signal analyzer.

AC Probe (Low Frequency)

The Agilent 41800A low frequency probe has a low input capacitance and a frequency range of 5 Hz to 500 MHz.
Broadband Preamplifiers and Power Amplifiers

Preamplifiers and power amplifiers can be used with your signal analyzer to enhance measurements of very low-level signals.

• The Agilent 8447D preamplifier provides a minimum of 25 dB gain from 100 kHz to 1.3 GHz.
• The Agilent 87405A preamplifier provides a minimum of 22 dB gain from 10 MHz to 3 GHz. (Power is supplied by the probe power output of the analyzer.)
• The Agilent 83006A preamplifier provides a minimum of 26 dB gain from 10 MHz to 26.5 GHz.
• The Agilent 85905A CATV 75 ohm preamplifier provides a minimum of 18 dB gain from 45 MHz to 1 GHz. (Power is supplied by the probe power output of the analyzer.)
• The 11909A low noise preamplifier provides a minimum of 32 dB gain from 9 kHz to 1 GHz and a typical noise figure of 1.8 dB.

GPIB Cable

The Agilent 10833 Series GPIB cables interconnect GPIB devices and are available in four different lengths (0.5 to 4 meters). GPIB cables are used to connect controllers to a signal analyzer.

USB/GPIB Cable

The Agilent 82357A USB/GPIB interface provides a direct connection from the USB port on your laptop or desktop PC to GPIB instruments. It comes with the SICL and VISA software for Windows® 2000/XP. Using VISA software, your existing GPIB programs work immediately, without modification. The 82357A is a standard Plug and Play device and you can interface with up to 14 GPIB instruments.

RF and Transient Limiters

The Agilent 11867A and N9355B RF and Microwave Limiters protect the analyzer input circuits from damage due to high power levels. The N9355B operates over a frequency range of dc to 1800 MHz and begins reflecting signal levels over 1 mW up to 10 W average power and 100 watts peak power. The 11693A microwave limiter (0.1 to 18 GHz) guards against input signals over 10 milliwatt up to 1 watt average power.

The Agilent 11947A Transient Limiter protects the analyzer input circuits from damage due to signal transients. It specifically is needed for use with a line impedance stabilization network (LISN). It operates over a frequency range of 9 kHz to 200 MHz, with 10 dB of insertion loss.
Accessories Available

**Power Splitters**

The Agilent 11667A/B/C power splitters are two-resistor type splitters that provide excellent output SWR, at 50 Ω impedance. The tracking between the two output arms, over a broad frequency range, allows wideband measurements to be made with a minimum of uncertainty.

- 11667A: DC to 18 GHz
- 11667B: DC to 26.5 GHz
- 11667C: DC to 50 GHz

**Static Safety Accessories**

- 9300-1367  Wrist-strap, color black, stainless steel. Four adjustable links and a 7 mm post-type connection.
- 9300-0980  Wrist-strap cord 1.5 m (5 ft.)
2 Measuring Multiple Signals
Comparing Signals on the Same Screen Using Marker Delta

Using the analyzer, you can easily compare frequency and amplitude differences between signals, such as radio or television signal spectra. The analyzer delta marker function lets you compare two signals when both appear on the screen at one time.

In this procedure, the analyzer 10 MHz signal is used to measure frequency and amplitude differences between two signals on the same screen. Delta marker is used to demonstrate this comparison.

**Figure 2-1  An Example of Comparing Signals on the Same Screen**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Connect the 10 MHz OUT from the rear panel to the front panel RF input.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Select the mode.</td>
<td>a. Press <strong>Mode, Spectrum Analyzer</strong>.</td>
</tr>
<tr>
<td>3</td>
<td>Preset the mode.</td>
<td>a. Press <strong>Mode Preset</strong>.</td>
</tr>
</tbody>
</table>
| 4    | Configure the analyzer settings. | a. Press **FREQ Channel, Center Freq**, 30, MHz.  
   b. Press **SPAN X Scale, Span**, 50, MHz.  
   c. Press **AMPTD Y Scale, Ref Level**, 10, dBm.  
   This sets the analyzer center frequency, span and reference level to view the 10 MHz signal and its harmonics up to 50 MHz. |
## Measuring Multiple Signals

### Comparing Signals on the Same Screen Using Marker Delta

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Place a marker at the highest peak on the display (10 MHz).</td>
<td>The <strong>Next Pk Right</strong> and <strong>Next Pk Left</strong> softkeys are available to move the marker from peak to peak. The marker should be on the 10 MHz reference signal.</td>
</tr>
<tr>
<td>6</td>
<td>Anchor the first marker and activate a second delta marker.</td>
<td>The symbol for the first marker is changed from a diamond to a cross with a label that now reads 2, indicating that it is the fixed marker (reference point). The second marker symbol is a diamond labeled 1Δ2, indicating it is the delta marker. When you first press the Delta key, both markers are at the same frequency with the symbols superimposed over each other. It is not until you move the delta marker to a new frequency that the different marker symbols are easy to discern.</td>
</tr>
<tr>
<td>7</td>
<td>Move the delta marker to another signal peak.</td>
<td>The amplitude and frequency <strong>difference</strong> between the markers is displayed in the marker results block of the screen. Refer to the upper right portion of the screen. See Figure 2-2.</td>
</tr>
</tbody>
</table>
## Measuring Multiple Signals

### Comparing Signals on the Same Screen Using Marker Delta

**NOTE**

The frequency resolution of the marker readings can be increased by turning on the marker count function.

### Figure 2-2 Using the Delta Marker Function

<table>

<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>

![Figure 2-2 Using the Delta Marker Function](image-url)
Comparing Signals not on the Same Screen Using Marker Delta

Measure the frequency and amplitude difference between two signals that do not appear on the screen at one time. (This technique is useful for harmonic distortion tests when narrow span and narrow bandwidth are necessary to measure the low level harmonics.)

In this procedure, the analyzer 10 MHz signal is used to measure frequency and amplitude differences between one signal on screen and one signal off screen. Delta marker is used to demonstrate this comparison.

**Figure 2-3** Comparing One Signal on Screen with One Signal Off Screen

<table>
<thead>
<tr>
<th>Step</th>

Resolving Signals of Equal Amplitude

In this procedure a decrease in resolution bandwidth is used in combination with a decrease in video bandwidth to resolve two signals of equal amplitude with a frequency separation of 100 kHz. Notice that the final RBW selection to resolve the signals is the same width as the signal separation while the VBW is slightly narrower than the RBW.

<td>Change the RBW.</td>
<td>a. Press BW, Res BW, 100, kHz. The RBW setting is less than or equal to the frequency separation of the two signals.</td>
</tr>
<tr>
<td>7</td>
<td>Decrease the video BW.</td>
<td>a. Press Video BW, 10, kHz. Notice that the peak of the signal has become two peaks separated by a 2.5 dB dip indicating that two signals may be present. See Figure 2-6.</td>
</tr>
</tbody>
</table>
### Measuring Multiple Signals

#### Resolving Signals of Equal Amplitude

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Decrease the RBW.</td>
<td>Two signals are now visible, see Figure 2-7. You can use the front-panel knob or step keys to further reduce the resolution bandwidth and better resolve the signals.</td>
</tr>
</tbody>
</table>

8. Decrease the RBW.  
   a. Press **BW, Res BW, 10, kHz**.
As the resolution bandwidth is decreased, resolution of the individual signals is improved and the sweep time is increased. For fastest measurement times, use the widest possible resolution bandwidth. Under mode preset conditions, the resolution bandwidth is “coupled” (or linked) to the span.

Since the resolution bandwidth has been changed from the coupled value, a # mark appears next to Res BW in the lower-left corner of the screen, indicating that the resolution bandwidth is uncoupled. (For more information on coupling, refer to the Auto Couple key description in the Agilent Technologies X-Series User’s and Programmer’s Reference.)

**NOTE**

An alternative method for resolving two equal amplitude signals is to use the Auto Tune Function as follows:

Press **Mode Preset**.

Press **Freq Channel, Auto Tune**.

The two signals are fully resolved with a marker placed on the highest peak. Refer to Figure 2-8.
Figure 2-8  Resolving Signals of Equal Amplitude
Resolving Small Signals Hidden by Large Signals

This procedure uses narrow resolution bandwidths to resolve two input signals with a frequency separation of 50 kHz and an amplitude difference of 60 dB.

<td>Set up the analyzer to view the signals.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a. Press FREQ Channel, Center Freq, 300, MHz.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>c. Press SPAN X Scale, Span, 500, kHz.</td>
<td></td>
</tr>
</tbody>
</table>
### Measuring Multiple Signals

#### Resolving Small Signals Hidden by Large Signals

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>Set the 300 MHz signal peak to the reference level.</td>
<td>a. Press <strong>Peak Search, Mkr → Ref Lvl</strong>. The Signal Analyzer 30 kHz filter shape factor of 4.1:1 has a bandwidth of 123 kHz at the 60 dB point. The half-bandwidth, or 61.5 kHz, is NOT narrower than the frequency separation of 50 kHz, so the input signals cannot be resolved. See Figure 2-9.</td>
</tr>
</tbody>
</table>

**Figure 2-9**  
*Signal resolution with a 30 kHz RBW*

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>Change the RBW.</td>
<td>a. Press <strong>BW, Res BW, 10, kHz</strong>. The reduced resolution bandwidth filter allows you to view the smaller hidden signal.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Place a delta marker on the smaller signal.</td>
<td>a. Press <strong>Peak Search, Marker Delta, 50, kHz</strong>. Notice that the peak of the signal has become two peaks separated by a 2.5 dB dip indicating that two signals may be present. See Figure 2-10.</td>
</tr>
</tbody>
</table>
### Step 9

Decrease the RBW.

- **Action**: Press **BW, 10, kHz**.

**Notes**

The Signal Analyzer 10 kHz filter shape factor of 4.1:1 has a bandwidth of 4.1 kHz at the 60 dB point. The half-bandwidth, or 20.5 kHz, is narrower than 50 kHz, so the input signals can be resolved. See Figure 2-11.
### Measuring Multiple Signals

**Resolving Small Signals Hidden by Large Signals**

**NOTE**

To make the separate signals more clear in the display, you may need to use averaging. To set the averaging to 10 averages:

- Press **Meas Setup**.
- Press **Average/Hold Number, 10, Enter.**

<td>See Figure 2-13.</td>
</tr>
</tbody>
</table>

Figure 2-13  Signal Tracking After Zooming in on the Signal
Easily Measure Varying Levels of Modulated Power Compared to a Reference

This section demonstrates a method to measure the complex modulated power of a reference device or setup and then compare the result of adjustments and changes to that or other devices.

The Delta Band/Interval Power Marker function will be used to capture the simulated signal power of a reference device or setup and then compare the resulting power level due to adjustments or DUT changes.

An important key to making accurate Band Power Marker measurements is to insure that the Average Type under the Meas Setup key is set to “Auto”.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Connect the source RF OUTPUT to the analyzer RF INPUT as shown.</td>
<td></td>
</tr>
</tbody>
</table>
| 2    | Set up the signal sources.  
   a. Set up a 4-carrier W-CDMA signal.  
   b. Set the source frequency to 1.96 GHz.  
   c. Set the source amplitude to −10 dBm. |       |
| 3    | Select the mode.  
   a. Press Mode, Spectrum Analyzer. |       |
| 4    | Preset the analyzer.  
   a. Press Mode Preset. |       |
| 5    | Tune to W-CDMA signal.  
   a. Press FREQ Channel, Auto Tune, 300, MHz. |       |
| 6    | Set the analyzer reference level.  
   a. Press AMPTD Y Scale, Ref Level, 0, dBm. |       |
| 7    | Enable trace averaging.  
   a. Press Trace/Detector, Select Trace, Trace 1, Trace Average. |       |
### Step 8: Enable the Band/Interval Power Marker function.
- a. Press **Marker Function, Band/Interval Power**.
- **Notes**: This measures the total power of the reference 4-carrier W-CDMA signal.

### Step 9: Center the frequency of the Band/Interval Power marker.
- a. Press **Select Marker, Marker 1, 1.96, GHz**.
- **Notes**: This centers the marker on the 4-carrier reference signal envelope.

### Step 10: Adjust the width (or span) of the Band/Interval Power marker.
- a. Press **Marker Function, Band Adjust, Band/Interval Span, 20, MHz**.
- **Notes**: This encompasses the entire 4-carrier W-CDMA reference signal. See Figure 2-14.

Note the green vertical lines of Marker 1 representing the span of signals included in the Band/Interval Power measurement and the carrier power indicated in Markers Result Block.

**Figure 2-14**  
*Measured Power of Reference 4-carrier W-CDMA Signal Using Band/Interval Power Marker*
### Step 11: Enable the Delta Band Power Marker functionality.

**Action:**
- Press **Marker, Select Marker, Marker 1, Delta.**

**Notes:**
- This will change the reference Band Power Marker into a fixed power value (labeled X2) and initiate a second Band Power Marker (labeled 1 Δ 2) to measure any changes in power levels relative to the reference Band Power Marker X2.

### Step 12: Simulate a varying power level resulting from either adjustments, changes to the reference DUT, or a different DUT by lowering the signal source power.

**Action:**
- Set the source amplitude to –20 dBm.

**Notes:**
- Note the Delta Band Power Marker value displayed in the Marker Result Block showing the 10 dB difference between the modulated power of the reference and the changed power level.

See Figure 2-15

---

Measuring Multiple Signals

Easily Measure Varying Levels of Modulated Power Compared to a Reference
3 Measuring a Low-Level Signal
Reducing Input Attenuation

The ability to measure a low-level signal is limited by internally generated noise in the signal analyzer. The measurement setup can be changed in several ways to improve the analyzer sensitivity.

The input attenuator affects the level of a signal passing through the instrument. If a signal is very close to the noise floor, reducing input attenuation can bring the signal out of the noise.

**CAUTION**

Ensure that the total power of all input signals at the analyzer RF input does not exceed +30 dBm (1 watt).

<table>

| 5    | Set the center frequency, span and reference level. | a. Press **FREQ Channel, Center Freq, 300, MHz**. 
|      |        | b. Press **SPAN X Scale, Span, 50, MHz**. 
|      |        | c. Press **AMPTD Y Scale, Ref Level, 40, −dBm**. |
6 Decrease the RBW.  
   a. Press **BW, 47 kHz**. 
   The low-level signal appears more clearly because the noise level is reduced. See Figure 3-4.

A “#” mark appears next to the **Res BW** annotation in the lower left corner of the screen, indicating that the resolution bandwidth is uncoupled.
RBW Selections

You can use the step keys to change the RBW in a 1–3–10 sequence.

All the Signal Analyzer RBWs are digital and have a selectivity ratio of 4.1:1. Choosing the next lower RBW (in a 1–3–10 sequence) for better sensitivity increases the sweep time by about 10:1 for swept measurements, and about 3:1 for FFT measurements (within the limits of RBW). Using the knob or keypad, you can select RBWs from 1 Hz to 3 MHz in approximately 10% increments, plus 4, 5, 6 and 8 MHz. This enables you to make the trade off between sweep time and sensitivity with finer resolution.
# Measuring a Low-Level Signal

**Using the Average Detector and Increased Sweep Time**

When the analyzer noise masks low-level signals, changing to the average detector and increasing the sweep time smooths the noise and improves the signal visibility. Slower sweeps are required to average more noise variations.

Varying the sweep time with the average detector
### Trace Averaging

Averaging is a digital process in which each trace point is averaged with the previous average for the same trace point. Selecting averaging, when the analyzer is autocoupled, changes the detection mode from normal to sample. Sample mode may not measure a signal amplitude as accurately as normal mode, because it may not find the true peak.

**NOTE**

This is a trace processing function and is not the same as using the average detector (as described on page 48).

*Figure 4-1 Using Marker Counter*

6 Turn off the marker counter.

a. Press **Marker, More, Marker Count, Count (Off)**.  
   Or  
   Press **Marker, Off**.
5 Tracking Drifting Signals
Measuring a Source Frequency Drift

The analyzer can measure the short- and long-term stability of a source. The maximum amplitude level and the frequency drift of an input signal trace can be displayed and held by using the maximum-hold function. You can also use the maximum hold function if you want to determine how much of the frequency spectrum a signal occupies.

This procedure using signal tracking to keep the drifting signal in the center of the display. The drifting is captured by the analyzer using maximum hold.

## Tracking a Signal

The signal track function is useful for tracking drifting signals that drift relatively slowly by keeping the signal centered on the display as the signal drifts. This procedure tracks a drifting signal.

Note that the primary function of the signal track function is to track unstable signals, not to track a signal as the center frequency of the analyzer is changed. If you choose to use the signal track function when changing center frequency, check to ensure that the signal found by the tracking function is the correct signal.

Identifying Analyzer Generated Distortion

High level input signals may cause internal analyzer distortion products that could mask the real distortion measured on the input signal. Using trace 2 and the RF attenuator, you can determine which signals, if any, are internally generated distortion products.

Using a signal from a signal generator, determine whether the harmonic distortion products are generated by the analyzer.

<table>

<tbody>
<tr>
<td>11 Increase the RF attenuation to 10 dB.</td>
<td>Press <strong>AMPTD Y Scale, Attenuation, 10, dB</strong>.</td>
<td>Notice the ΔMkr1 amplitude reading. This is the difference in the distortion product amplitude readings between 0 dB and 10 dB input attenuation settings. If the ΔMkr1 amplitude absolute value is approximately ≥1 dB for an input attenuator change of 10 dB, the distortion is being generated, at least in part, by the analyzer. In this case more input attenuation is necessary. Increase the input attenuation until ΔMkr1 amplitude stops increasing or decreasing in value. Return to the previous attenuator step and the input signal distortion measured will be minimally impacted by the analyzer internally generated distortion. See Figure 6-2.</td>
</tr>
</tbody>
</table>

*Figure 6-2 RF Attenuation of 10 dB*
Third-Order Intermodulation Distortion

Two-tone, third-order intermodulation distortion is a common test in communication systems. When two signals are present in a non-linear system, they can interact and create third-order intermodulation distortion products that are located close to the original signals. These distortion products are generated by system components such as amplifiers and mixers.

This procedure tests a device for third-order intermodulation using markers. Two sources are used, one set to 300 MHz and the other to 301 MHz. This combination of signal generators and a directional coupler (used as a combiner) results in a two-tone source with very low intermodulation distortion. Although the distortion from this setup may be better than the specified performance of the analyzer, it is useful for determining the TOI performance of the source/ analyzer combination. After the performance of the source/analyzer combination has been verified, the device-under-test (DUT) (for example, an amplifier) would be inserted between the directional coupler output and the analyzer input.

<table>

7 Measuring Noise
Measuring Signal-to-Noise

Signal-to-noise is a ratio used in many communication systems as an indication of noise in a system. Typically the more signals added to a system adds to the noise level, reducing the signal-to-noise ratio making it more difficult for modulated signals to be demodulated. This measurement is also referred to as carrier-to-noise in some communication systems.

The signal-to-noise measurement procedure below may be adapted to measure any signal in a system if the signal (carrier) is a discrete tone. If the signal in your system is modulated, it is necessary to modify the procedure to correctly measure the modulated signal level.

In this example the 50 MHz amplitude reference signal is used as the fundamental signal. The amplitude reference signal is assumed to be the signal of interest and the internal noise of the analyzer is measured as the system noise. To do this, you need to set the input attenuator such that both the signal and the noise are well within the calibrated region of the display.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the analyzer to the Spectrum Analyzer mode. a. Press <strong>Mode, Spectrum Analyzer</strong>.</td>
<td>This enables the spectrum analyzer measurements.</td>
</tr>
<tr>
<td>2</td>
<td>Preset the analyzer. a. Press <strong>Mode Preset</strong>.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Enable the internal reference signal. a. Press <strong>Input/Output, RF Calibrator, 50, MHz</strong>.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Set the center frequency, span, reference level and attenuation. a. Press <strong>FREQ Channel, Center Freq, 50, MHz</strong>. b. Press <strong>SPAN X Scale, Span, 1, MHz</strong>. c. Press <strong>AMPTD Y Scale, Ref Level, −10, dBm</strong>. d. Press <strong>AMPTD Y Scale, Attenuation, 40, dB</strong>.</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Place a marker on the peak of the signal and place a delta marker in the noise. a. Press <strong>Peak Search, Marker Delta, 200, kHz</strong>.</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Turn on the marker noise function. a. Press <strong>Marker Function, Marker Noise</strong>.</td>
<td>This enables you to view the signal-to-noise measurement results.</td>
</tr>
</tbody>
</table>
Read the signal-to-noise in dB/Hz, that is with the noise value determined for a 1 Hz noise bandwidth. If you wish the noise value for a different bandwidth, decrease the ratio by $10 \times \log(BW)$ . For example, if the analyzer reading is $-70$ dB/Hz but you have a channel bandwidth of 30 kHz:

$$S/N = -70 \text{ dB/Hz} + 10 \times \log(30 \text{ kHz}) = -25.23 \text{ dB/(30 kHz)}$$

**NOTE**

When Noise Marker is activated, the display detection mode is set to Average.

**NOTE**

When using the Noise Marker, if the delta marker is closer than one quarter of a division from the edge of a discrete signal response, the amplitude reference signal in this case, there is a potential for error in the noise measurement. See “Measuring Noise Using the Noise Marker” on page 72.
Measuring Noise Using the Noise Marker

This procedure uses the marker function, **Marker Noise**, to measure noise in a 1 Hz bandwidth. In this example the noise marker measurement is made near the 50 MHz reference signal to illustrate the use of **Marker Noise**.

# Measuring Noise-Like Signals Using the Channel Power Measurement

You may want to measure the total power of a noise-like signal that occupies some bandwidth. Typically, channel power measurements are used to measure the total (channel) power in a selected bandwidth for a modulated (noise-like) signal. Alternatively, to manually calculate the channel power for a modulated signal, use the noise marker value and add $10 \times \log_{10}(\text{channel BW})$. However, if you are not certain of the characteristics of the signal, or if there are discrete spectral components in the band of interest, you can use the channel power measurement. This example uses the noise of the analyzer, adds a discrete tone, and assumes a channel bandwidth (integration bandwidth) of 2 MHz. If desired, a specific signal may be substituted.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the analyzer to the Spectrum Analyzer mode.</td>
<td>a. Press <strong>Mode, Spectrum Analyzer</strong>. This enables the spectrum analyzer measurements.</td>

<tr>
<td>5</td>
<td>Enable the bar graph.</td>
<td>a. Press <strong>View/Display, Bar Graph, On</strong>.</td>
</tr>
<tr>
<td>6</td>
<td>Enable the internal 50 MHz amplitude reference signal.</td>
<td>Press <strong>Input/Output, RF Calibrator, 50 MHz</strong>. This adds a discrete tone to see the effects on the reading.</td>
</tr>
</tbody>
</table>
| 7    | Optimize the analyzer attenuation level setting. | a. Press **AMPTD, Attenuation, Adjust Atten for Min Clip**. Your display should be similar to Figure 7-6.
The power reading is essentially that of the tone; that is, the total noise power is far enough below that of the tone that the noise power contributes very little to the total. The algorithm that computes the total power works equally well for signals of any statistical variant, whether tone-like, noise-like, or combination.
Measuring Signal-to-Noise of a Modulated Carrier

Signal-to-noise (or carrier-to-noise) is a ratio used in many communication systems as indication of the noise performance in the system. Typically, the more signals added to the system or an increase in the complexity of the modulation scheme can add to the noise level. This can reduce the signal-to-noise ratio and impact the quality of the demodulated signal. For example, a reduced signal-to-noise in digital systems may cause an increase in EVM (error vector magnitude).

With modern complex digital modulation schemes, measuring the modulated carrier requires capturing all of its power accurately. This procedure uses the Band Power Marker with a RMS average detector to correctly measure the carrier’s power within a user adjustable region. A Noise Marker (normalized to a 1 Hz noise power bandwidth) with an adjustable noise region is also employed to allow the user to select and accurately measure just the system noise of interest. An important key to making accurate Band Power Marker and Noise Power measurements is to insure that the Average Type under the Meas Setup key is set to “Auto”.

In this example a 4 carrier W-CDMA digitally modulated carrier is used as the fundamental signal and the internal noise of the analyzer is measured as the system noise.

Improving Phase Noise Measurements by Subtracting Signal Analyzer Noise

Making noise power measurements (such as phase noise) near the noise floor of the signal analyzer can be challenging where every dB improvement is important. Utilizing the analyzer trace math function Power Diff and 3 separate traces allows measurement of the DUT phase noise in one trace, the analyzer noise floor in a second trace and then the resulting subtraction of those two traces displayed in a third trace with the analyzer noise contribution removed.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1    | Setup the signal sources. | a. Setup an unmodulated signal.  
b. Set the source frequency to 1.96 GHz.  
c. Set the source amplitude to –30 dBm. |
| 2    | Instrument setup. | a. Connect the source RF OUTPUT to the analyzer RF INPUT as shown. |
| 3    | Set the analyzer to the Spectrum Analyzer mode. | a. Press Mode, Spectrum Analyzer.  
Note: This enables the spectrum analyzer measurements. |
| 4    | Preset the analyzer. | a. Press Mode Preset. |
| 5    | Tune to the unmodulated carrier, adjust the span and RBW. | a. Press FREQ Channel, Auto Tune.  
b. Press Span, Span, 200, kHz.  
| 6    | Measure and store the DUT phase noise plus the analyzer noise. | a. Press Trace/Detector, Select Trace, Trace 1, Trace Average  
After sufficient averaging:  
b. Press View/Blank, View  
Allow time for sufficient averaging before initiating action b.  
See Figure 7-11. |
Measure only the analyzer noise using trace 2 (blue trace) with trace averaging.

7 Measure only the analyzer noise using trace 2 (blue trace) with trace averaging.

a. Turn off or remove the DUT signal to the RF input of the analyzer.

b. Press Trace/Detector, Select Trace, Trace 2, Clear Write, Trace Average. Allow time for sufficient averaging.

c. Press View/Blank, View. See Figure 7-12.
Subtract the noise from the DUT phase noise measurement using the Power Diff math function.

- Press Trace/Detector, Select Trace, Trace 3, Clear Write.
- Press More, More, Math, Power Diff, Trace Operands, Operand 1, Trace 1, Operand 2, Trace 2.

Notice the phase noise improvement at 100 kHz offset between trace 1 (yellow trace) and trace 3 (magenta trace).
See Figure 7-13.

**Image Description:**
- The figure shows a spectrum analyzer display with delta noise markers.
- The reference level is set to -21.85 dBm.
- The noise level is approximately -5.85 dB.
- The marker function is highlighted with an arrow on the right side.
Traditional frequency-domain spectrum analysis provides only limited information for certain signals. Examples of these difficult-to-analyze signal include the following:

- Pulsed-RF
- Time multiplexed
- Interleaved or intermittent
- Time domain multiple access (TDMA) radio formats
- Modulated burst

The time gating measurement examples use a simple frequency-modulated, pulsed-RF signal. The goal is to eliminate the pulse spectrum and then view the spectrum of the FM carrier as if it were continually on, rather than pulsed. This reveals low-level modulation components that are hidden by the pulse spectrum.
Generating a Pulsed-RF FM Signal

When performing these measurements you can use a digitizing oscilloscope or your Agilent X-Series Signal Analyzer (using Gate View) to set up the gated signal. Refer back to these first three steps to set up the pulse signal, the pulsed-RF FM signal and the oscilloscope settings when performing the gated LO procedure (page 98), the gated video procedure (page 102) and gated FFT procedure (page 106).

For an instrument block diagram and instrument connections see “Connecting the Instruments to Make Time-Gated Measurements” on page 97.

Signal source setup

Step 1. Set up the pulse signal with a period of 5 ms and a width of 4 ms:

There are many ways to create a pulse signal. This example demonstrates how to create a pulse signal using a pulse generator or by using the internal function generator in the ESG. See Table 8-1 if you are using a pulse generator or Table 8-2 if you are using a second ESG. Select either the pulse generator or a second ESG to create the pulse signal.

Table 8-1 81100 Family Pulse Generator Settings

<table>
<thead>
<tr>
<th>Period</th>
<th>5 ms (or pulse frequency equal to 200 Hz)</th>
</tr>
</thead>
<tbody>

<tr>
<td>LF Out</td>
<td>On</td>
</tr>
<tr>
<td>RF On/Off</td>
<td>Off</td>
</tr>
<tr>
<td>Mod On/Off</td>
<td>On</td>
</tr>
</tbody>
</table>
Step 2. Set up ESG #1 to transmit a pulsed-RF signal with frequency modulation. Set the FM deviation to 1 kHz and the FM rate to 50 kHz.

ESG #1 generates the pulsed FM signal by frequency modulating the carrier signal and then pulse modulating the FM signal. The pulse signal created in step 1 is connected to the EXT 2 INPUT (on the front of ESG #1). The ESG RF OUTPUT is the pulsed-RF FM signal to be analyzed by the spectrum analyzer.

Figure 8-3  Viewing the Gate Timing with an Oscilloscope

Figure 8-3 oscilloscope channels:

1. Channel 1 (yellow trace) - the trigger signal.
2. Channel 2 (green trace) - the gate signal (gate signal is not active until the gate is on in the spectrum analyzer).
3. Channel 3 (purple) - the RF output of the signal generator.
Connecting the Instruments to Make Time-Gated Measurements

Figure 8-4 shows a diagram of the test setup. ESG #1 produces a pulsed FM signal by using an external pulse signal. The external pulse signal is connected to the front of the ESG #1 to the EXT 2 INPUT to control the pulsing. The pulse signal is also used as the trigger signal. The oscilloscope is useful for illustrating timing interactions between the trigger signal and the gate. The Gate View feature of the X-Series signal analyzer could be used in place of the oscilloscope.

Using this measurement setup allows you to view all signal spectra on the spectrum analyzer and all timing signals on the oscilloscope. This setup is helpful when you perform gated measurements on unknown signals. If an oscilloscope is not available, begin by using the Gate View feature to set up the gate parameters and then turn Gate View Off to view the signal spectra, refer to Figure 8-5.

Figure 8-4 Instrument Connection Diagram with Oscilloscope

Figure 8-5 Instrument Connection Diagram without Oscilloscope
### Gated LO Measurement

This procedure utilizes gated LO to gate the FM signal. For concept and theory information about gated LO see “How Time Gating Works” on page 149.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the analyzer to the Spectrum Analyzer mode.</td>
<td>a. Press <strong>Mode, Spectrum Analyzer</strong>. This enables the spectrum analyzer measurements.</td>
</tr>
<tr>
<td>2</td>
<td>Preset the analyzer.</td>
<td>a. Press <strong>Mode Preset</strong>.</td>
</tr>
</tbody>
</table>
| 3    | Set the center frequency, span, reference level and attenuation. | a. Press **FREQ Channel, Center Freq, 40, MHz**.  
     b. Press **SPAN X Scale, Span, 500, kHz**.  
     c. Press **AMPTD Y Scale, Ref Level, 10, dBm**. |
| 4    | Set the gate source to the rear external trigger input. | a. Press **Sweep/Control, Gate, More, Gate Source, External 1**. |
| 5    | Set the gate delay, gate length, gate sweep time, and gate trigger. | a. Press **Sweep/Control, Gate, Gate Delay, 2, ms**.  
     b. Press **Gate Length, 1, ms**.  
     c. Press **Gate View Sweep Time, 5, ms**.  
     d. Press **More1 of 2, Control (Edge)**. |
| 6    | Access the analyzer gate view display. | a. Press **Sweep/Control, Gate, Gate View (On)**. Use this function to confirm the gate “on” time during the RF burst interval (alternatively you could also use the oscilloscope to view the gate settings). |
The blue vertical line (the far left line outside of the RF envelope) represents the location equivalent to a zero gate delay.

The vertical green parallel bars represent the gate settings. The first (left) bar (GATE START) is set at the delay time while the second (right) bar (GATE STOP) is set at the gate length, measured from the first bar. The trace of the signal in this time-domain view is the RF envelope. The gate signal is triggered off of the positive edge of the trigger signal.

When positioning the gate, a good starting point is to have it extend from 20% to 80% of the way through the pulse.

While gate view mode is on, move the gate delay, length and polarity around. Notice the changes in the vertical gate bars while making your changes. Set the gate delay, length and polarity back to the step 3 settings.

NOTE The analyzer time gate triggering mode uses positive edge, negative edge, and level triggering.

7 Turn the gate view off.
   a. Press Sweep/Control, Gate, Gate View (Off).

See Figure 8-7.
Making Time-Gated Measurements

Gated LO Measurement

The moving signals are a result of the pulsed signal. Using delta markers with a time readout, notice that the period of the spikes is at 5 ms (the same period as the pulse signal). Using time gating, these signals will be blocked out, leaving the original FM signal.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>

Making Time-Gated Measurements

Gated Video Measurement

This procedure utilizes gated video to gate the FM signal. For concept and theory information about gated video see “How Time Gating Works” on page 148.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the analyzer to the Spectrum Analyzer mode.</td>
<td>This enables the spectrum analyzer measurements.</td>
</tr>
<tr>
<td></td>
<td>a. Press <strong>Mode, Spectrum Analyzer</strong>.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Preset the analyzer</td>
<td>a. Press <strong>Mode Preset</strong>.</td>
</tr>
</tbody>
</table>
| 3    | Set the center frequency, span, reference level and attenuation. | a. Press **FREQ Channel, Center Freq, 40, MHz**.  
|      |      | b. Press **SPAN X Scale, Span, 500, kHz**.  
|      |      | c. Press **AMPTD Y Scale, Ref Level, 10, dBm**. |
| 4    | Set analyzer points to 401 and sweep time to 2000 ms. | a. Press **Sweep/Control, Points, 401, Enter**.  
|      |      | b. Press **Sweep Time, 2000, ms**. |
|      | For gated video, the calculated sweep time should be set to at least $(#\text{sweep points} - 1) \times PRI$ (pulse repetition interval) to ensure that the gate is on at least once during each of the 401 sweep points. In this example, the PRI is 5 ms, so you should set the sweep time to 401 minus 1 times 5 ms, or 2 s. If the sweep time is set too fast, some trace points may show values of zero power or other incorrect low readings. If the trace seems incomplete or erratic, try a longer sweep time. |
| 5    | Set the Gate source to the external trigger input on the rear panel: | a. Press **Sweep/Control, Gate, More, Gate Source, External 1**. |

**Good practices for determining the minimum sweep time for gated video:**

In the event that the signal is not noisy, the sweep time can be set to less than $(#\text{sweep points} - 1) \times PRI$ (as calculated above). Instead of using PRI in the previous sweep time calculation, we can use the “gate off time” where sweep time equals $(#\text{sweep points} - 1) \times \text{gate off time}$ . (Gate off time is defined as $PRI - \text{GL}$, where GL = Gate Length.) In our example we could use a sweep time of 400 points times 1 ms or 400 ms – $(401 - 1) \times (5\text{ms} - 4\text{ms}) = 400\text{ms}$ . Increase the video bandwidth to improve the probability of capturing the pulse using “gate off time”. If trace points are still showing values of zero power, increase the sweep time by small increments until there are no more dropouts.
6 Set the gate delay and gate length.
   a. Press **Sweep/Control**, **Gate**, **More**, **Control** (Edge).
   c. Press **Gate Length**, 1, ms.

   Ensure that the gate control is set to Edge.

7 Turn the gate on.
   a. Press **Sweep/Control**, **Gate**, **Gate Method**, **Video**.
   b. Press **Gate** (On).
Making Time-Gated Measurements

Gated Video Measurement

Notice that the gated spectrum is much cleaner than the ungated spectrum (as seen in Figure 8-9). The spectrum you see is the same as a frequency modulated signal without being pulsed. To prove this, turn off the pulse modulation on ESG #1 by pressing Pulse, Pulse so that Off is selected. The displayed spectrum does not change.

If you have used an oscilloscope, check the oscilloscope display and ensure that the gate is positioned under the pulse. The gate should be set so that it is on somewhere between 20% to 80% of the pulse. If necessary, adjust gate length and gate delay. Figure 8-11 shows the oscilloscope display when the gate is positioned correctly (the bottom trace).
<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>

**Figure 8-11** The Oscilloscope Display

![Oscilloscope Display Image]
Gated FFT Measurement

This procedure utilizes gated FFT to gate the FM signal. For concept and theory information about gated FFT see “How Time Gating Works” on page 149.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the analyzer to the Spectrum Analyzer mode.</td>
<td>a. Press <strong>Mode, Spectrum Analyzer</strong>. This enables the spectrum analyzer measurements.</td>
</tr>
<tr>
<td>2</td>
<td>Preset the analyzer</td>
<td>a. Press <strong>Mode Preset</strong>.</td>
</tr>
</tbody>
</table>
| 3    | Set the center frequency, span, reference level and attenuation. | a. Press **FREQ Channel, Center Freq, 40, MHz**.  
b. Press **SPAN X Scale, Span, 500, kHz**.  
c. Press **AMPTD Y Scale, Ref Level, 10, dBm**. |
| 4    | Set the Gate source to the external trigger input on the rear panel. | a. Press **Sweep/Control, Gate, More, Gate Source, External 1**. |
| 5    | Set the gate method and turn gate on. | a. Press **Sweep/Control, Gate, Gate Method, FFT**.  
b. Press **Gate (On)**. |
| 6    | Select the minimum resolution bandwidth required. | a. Press **BW, Res BW (Auto)**. See **Figure 8-12**. |
The duration of the analysis required is determined by the RBW. Divide 1.83 by 4 ms to calculate the minimum RBW. The pulse width in our case is 4 ms so we need a minimum RBW of 458 Hz. In this case because the RBW is so narrow let the analyzer choose the RBW for the current analyzer settings (span). Check that the RBW is greater than 458 Hz. Vary the RBW settings and note the signal changes shape as the RBW transitions from 1 kHz to 300 Hz.

**NOTE** If the trigger event needs to be delayed use the *Trig Delay* function under the *Trigger* menu. Apply some small amount of trigger delay to allow time for the device under test to settle.
Making Time-Gated Measurements

Gated FFT Measurement
The Signal Analyzer makes power measurements on digital communication signals fast and repeatable by providing a comprehensive suite of power-based one-button automated measurements with pre-set standards-based format setups. The automated measurements also include pass/fail functionality that allow the user to quickly check if the signal passed the measurement.
**Channel Power Measurements**

This section explains how to make a channel power measurement on a W-CDMA (3GPP) mobile station. (A signal generator is used to simulate a base station.) This test measures the total RF power present in the channel. The results are displayed graphically as well as in total power (dB) and power spectral density (dBm/Hz).

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1    | Set up the signal generator. | a. Set the mode to W-CDMA.  
b. Set the frequency to 1.920 GHz.  
c. Set the amplitude to –20 dBm. |
| 2    | Connect the source RF OUTPUT to the analyzer RF INPUT as shown. |
| 3    | Select the mode. | a. Press **Mode, Spectrum Analyzer**. |
| 4    | Preset the analyzer. | a. Press **Mode Preset**. |
| 5    | Set the radio standard and toggle the device to mobile station. | a. Press **Mode Setup, Radio Std, 3GPP W-CDMA, 3GPP W-CDMA, Device (MS)**. |
| 6    | Set the center frequency. | a. Press **FREQ Channel, 1.920, GHz**. |
| 7    | Initiate the channel power measurement. | a. Press **Meas, Channel Power**. The Channel Power measurement result should look like “Channel Power Measurement Result.” on page 111. |
The graph window and the text window showing the absolute power and its mean power spectral density values over 5 MHz are displayed.

To change the measurement parameters from their default condition:

Press **Meas Setup**.
This section explains how to make the occupied bandwidth measurement on a W-CDMA (3GPP) mobile station. (A signal generator is used to simulate a base station.) The instrument measures power across the band, and then calculates its 99.0% power bandwidth.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1 | Set up the signal generator. | a. Set the mode to W-CDMA.  
b. Set the frequency to 1.920 GHz.  
c. Set the amplitude to −20 dBm. |
| 2 | Connect the source RF OUTPUT to the analyzer RF INPUT as shown. | |
| 3 | Select the mode. | a. Press Mode, Spectrum Analyzer. |
| 4 | Preset the analyzer. | a. Press Mode Preset. |
| 5 | Set the radio standard and toggle the device to mobile station. | a. Press Mode Setup, Radio Std, 3GPP W-CDMA, 3GPP W-CDMA, Device (MS). |

| 7 | Initiate the occupied bandwidth measurement. | a. Press Meas, Occupied BW. The Occupied BW measurement result should look like “Occupied BW Measurement Result” on page 113. |
**Troubleshooting Hints**

Any distortion such as harmonics or intermodulation, for example, produces undesirable power outside the specified bandwidth.

Shoulders on either side of the spectrum shape indicate spectral regrowth and intermodulation. Rounding or sloping of the top shape can indicate filter shape problems.
### Making Adjacent Channel Power (ACP) Measurements

The adjacent channel power (ACP) measurement is also referred to as the adjacent channel power ratio (ACPR) and adjacent channel leakage ratio (ACLR). We use the term ACP to refer to this measurement.

ACP measures the total power (rms voltage) in the specified channel and up to six pairs of offset frequencies. The measurement result reports the ratios of the offset powers to the main channel power.

The following example shows how to make an ACP measurement on a W-CDMA base station signal broadcasting at 1.96 GHz. (A signal generator is used to simulate a base station.)

### NOTE
You may increase the repeatability by increasing the sweep time.
Making Statistical Power Measurements (CCDF)

Complementary cumulative distribution function (CCDF) curves characterize a signal by providing information about how much time the signal spends at or above a given power level. The CCDF measurement shows the percentage of time a signal spends at a particular power level. Percentage is on the vertical axis and power (in dB) is on the horizontal axis.

All CDMA signals, and W-CDMA signals in particular, are characterized by high power peaks that occur infrequently. It is important that these peaks are preserved otherwise separate data channels can not be received properly. Too many peak signals can also cause spectral regrowth. If a CDMA system works well most of the time and only fails occasionally, this can often be caused by compression of the higher peak signals.

The following example shows how to make a CCDF measurement on a W-CDMA signal broadcasting at 1.96 GHz. (A signal generator is used to simulate a base station.)

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>

</thead>
</table>
| 1    | Setup the signal source. | a. Setup a Bluetooth™ signal transmitting DH1 packets.  
b. Set the source frequency to 2.402 GHz.  
c. Set the source amplitudes to −10 dBm.  
d. Set the source amplitudes to −10 dBm. |
| 2    | Connect the source RF OUTPUT to the analyzer RF INPUT as shown. |
| 3    | Set the analyzer to the Spectrum Analyzer mode. | a. Press **Mode, Spectrum Analyzer**. |
| 4    | Preset the analyzer. | a. Press **Mode Preset**. |
| 5    | Set the analyzer center frequency. | a. Press **FREQ Channel, Center Freq**, 2.402, GHz. |
| 6    | Set the analyzer radio mode to Bluetooth™. | a. Press **Mode Setup, Radio Std, More, Bluetooth, Bluetooth, DH1**.  
Check to make sure packet type DH1 is selected. |
| 7    | Select the burst power measurement and optimize the attenuation level. | a. Press **Meas, Burst Power**.  
b. Press **AMPTD, Attenuation, Adjust Atten for Min Clip**. |
View the results of the burst power measurement using the full screen.

**a. Press Full Screen.**

See Figure 9-10.

---

**NOTE**

Press the Full Screen key again to exit the full screen display without changing any parameter values. Refer to Figure 9-11.

---

**Step** | **Action** | **Notes**
--- | --- | ---
8 | View the results of the burst power measurement using the full screen. | See Figure 9-10.

**Figure 9-10**

*Full Screen Display of Burst Power Measurement Results*

NOTE: Press the Full Screen key again to exit the full screen display without changing any parameter values. Refer to Figure 9-11.
Select one of the following three trigger methods to capture the bursted signal:

- Periodic Timer Triggering
- Video
- RF Burst Wideband Triggering (RF burst is recommended, if available.)

Set the relative threshold level above which the burst power measurement is calculated.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>a. Press <strong>Trigger, RF Burst</strong>. For more information on trigger selections see “Trigger Concepts” on page 160. Although the trigger level allows the analyzer to detect the presence of a burst, the time samples contributing to the burst power measurement are determined by the threshold level, as described next.</td>
</tr>
<tr>
<td>10</td>
<td>a. Press <strong>Meas Setup, Threshold Lvl (Rel), −10, dB</strong>. The burst power measurement includes all points above the threshold and no points below. The threshold level is indicated on the display by the green horizontal line. In this example, the threshold level has been set to be 10 dB below the relative level of the burst. The mean power of the burst is measured from all data above the threshold level. Refer to <strong>Figure 9-12</strong>.</td>
</tr>
</tbody>
</table>
11 Set the burst width to measure the central 200 µs of the burst and enable bar graph.

1. Press **View/Display Bar Graph (On)**.
2. Press **Meas Setup, Meas Method, Measured Burst Width, Burst Width (Man), 200, µs**.

   The burst width is indicated on the screen by two vertical white lines and a blue power bar. Manually setting the burst width allows you to make it a long time interval (to include the rising and falling edges of the burst) or to make it a short time interval, measuring a small central section of the burst. Refer to **Figure 9-13**.
### NOTES

If you set the burst width manually to be wider than the screen’s display, the vertical white lines move off the edges of the screen. This could give misleading results as only the data on the screen can be measured.

The Bluetooth™ standard states that power measurements should be taken over at least 20% to 80% of the duration of the burst.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 12.0 | Increase the sweep time to display more than one burst at a time. | Press **Sweep/Control, Sweep Time, 6200. μs (or 6.2, ms)**. The screen display shows several bursts in a single sweep as in **Figure 9-14**. The burst power measurement measures the mean power of the first burst, indicated by the vertical white lines and blue power bar.
### Step 9.14: Displaying Multiple Bursts

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong> Although the burst power measurement still runs correctly when several bursts are displayed simultaneously, the timing accuracy of the measurement is degraded. For the best results (including the best trade-off between measurement variations and averaging time), it is recommended that the measurement be performed on a single burst.</td>
</tr>
</tbody>
</table>
### Spurious Emissions Measurements

The following example demonstrates how to make a spurious emissions measurement on a multitone signal used to simulate a spurious emission in a measured spectrum.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1    | Setup the signal source. | a. Setup a multitone signal with 8 tones with a 2.0 MHz frequency spacing.  
     |        | b. Set the source frequency to 1.950 GHz.  
     |        | c. Set the source amplitudes to −50 dBm. |
| 2    | Connect the source RF OUTPUT to the analyzer RF INPUT as shown. | |
| 3    | Set the analyzer to the Spectrum Analyzer mode. | a. Press **Mode, Spectrum Analyzer**. |
| 4    | Preset the analyzer. | a. Press **Mode Preset**. |
| 5    | Set the analyzer center frequency. | a. Press **FREQ Channel, Center Freq. 1.950, GHz**. |
| 6    | Select the spurious emissions measurement. | a. Press **Meas, More, Spurious Emissions**. |
**Step 7** You may Focus the display on a specific spurious emissions signal.

a. Press **Meas Setup, Spur, 1,** Enter (or enter the number of the spur of interest)

b. Press **Meas Type** to highlight **Examine**

The Spurious Emission result should look like Figure 9-15. The graph window and a text window are displayed. The text window shows the list of detected spurs. Each line item includes the spur number, the range in which the spur was detected, the power of the spur, and the limit value against which the spur amplitude is tested.

**Figure 9-15** *Spurious Emission Measurement Result*

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>You may Focus the display on a specific spurious emissions signal.</td>
<td>The Spurious Emission result should look like Figure 9-15. The graph window and a text window are displayed. The text window shows the list of detected spurs. Each line item includes the spur number, the range in which the spur was detected, the power of the spur, and the limit value against which the spur amplitude is tested.</td>
</tr>
</tbody>
</table>

**Step 8** You may customize the tested ranges for spurious emissions (initially 5 default ranges and parameters are loaded into the range table).

a. Press **Meas Setup, Range Table,** then select and edit the available parameters.
Troubleshooting Hints

Spurious emissions measurements can reveal the presence of degraded or defective parts in the transmitter section of the UUT. The following are examples of problems which, once indicated by testing, may require further attention:

• Faulty DC power supply control of the transmitter power amplifier
• RF power controller of the pre-power amplifier stage
• I/Q control of the baseband stage
• Reduction in the gain and output power level of the amplifier due to a degraded gain control and/or increased distortion
• Degradation of amplifier linearity and other performance characteristics

Power amplifiers are one of the final stage elements of a base transmitter and play a critical part in meeting the important power and spectral efficiency specifications. Measuring the spectral response of these amplifiers to complex wideband signals is crucial to linking amplifier linearity and other performance characteristics to the stringent system specifications.
This section explains how to make the spectrum emission mask measurement on a W-CDMA (3GPP) mobile station. (A signal generator is used to simulate a mobile station.) SEM compares the total power level within the defined carrier bandwidth and the given offset channels on both sides of the carrier frequency, to levels allowed by the standard. Results of the measurement of each offset segment can be viewed separately.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1    | Setup the signal source. | a. Setup a W-CDMA uplink signal.  
  b. Set the source frequency to 1.920 MHz (Channel Number: $5 \times 1,920 = 9,600$).  
  c. Set the source amplitudes to 0 dBm. |
| 2    | Connect the source RF OUTPUT to the analyzer RF INPUT as shown. |
| 3    | Select the mode. | a. Press Mode, Spectrum Analyzer. |
| 4    | Preset the analyzer. | a. Press Mode Preset. |
| 5    | Set the radio standard and toggle the device to mobile station. | a. Press Mode Setup, Radio Std, 3GPP W-CDMA, 3GPP W-CDMA, Device (MS). |
| 6    | Set the center frequency. | a. Press FREQ Channel, 1.920, GHz. |
### Troubleshooting Hints

This spectrum emission mask measurement can reveal degraded or defective parts in the transmitter section of the UUT. The following examples are those areas to be checked further.

- Faulty DC power supply control of the transmitter power amplifier.
- RF power controller of the pre-power amplifier stage.
- I/O control of the baseband stage.
- Some degradation in the gain and output power level of the amplifier due to the degraded gain control and/or increased distortion.
- Some degradation of the amplifier linearity or other performance characteristics.

<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>Initiate the spectrum emission mask measurement.</td>
<td>The Spectrum Emission Mask measurement result should look like Figure 9-16. The text window shows the reference total power and the absolute peak power levels which correspond to the frequency bands on both sides of the reference channel.</td>
</tr>
</tbody>
</table>

**Figure 9-16** Spectrum Emission Mask Measurement Result - (Default) View

![Spectrum Emission Mask Measurement Result](image-url)
Power amplifiers are one of the final stage elements of a base or mobile transmitter and are a critical part of meeting the important power and spectral efficiency specifications. Since spectrum emission mask measures the spectral response of the amplifier to a complex wideband signal, it is a key measurement linking amplifier linearity and other performance characteristics to the stringent system specifications.
10 Demodulating AM Signals
Measuring the Modulation Rate of an AM Signal

This section demonstrates how to determine parameters of an AM signal, such as modulation rate and modulation index (depth) by using frequency and time domain measurements (see the concepts chapter “AM and FM Demodulation Concepts” on page 182 for more information).

To obtain an AM signal, you can either connect a source transmitting an AM signal, or connect an antenna to the analyzer input and tune to a commercial AM broadcast station. For this demonstration an RF source is used to generate an AM signal.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Setup the signal source. a. Set the source frequency to 300 MHz. b. Set the source amplitudes to −10 dBm. c. Set the AM depth to 80%. d. Set the AM rate to 1 kHz. e. Turn AM on.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Connect an Agilent ESG RF signal source to the analyzer RF INPUT as shown.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Select the mode. a. Press Mode, Spectrum Analyzer.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Preset the analyzer. a. Press Mode Preset.</td>
<td></td>
</tr>
</tbody>
</table>
### Demodulating AM Signals

#### Measuring the Modulation Rate of an AM Signal

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 5    | Set the center frequency, span, RBW and the sweep time. | a. Press **FREQ Channel, Center Freq, 300, MHz.**  
b. Press **SPAN X Scale, Span, 500, kHz.**  
c. Press **BW, Res BW, 30, kHz.**  
d. Press **Sweep/Control, Sweep Time, 20, ms.** |
| 6    | Change the y-scale type to linear. | a. Press **AMPTD Y Scale, Scale Type (Lin).**  
The y-axis units will automatically set to volts. |
| 7    | Position the signal peak near the first graticule below the reference level. | a. Press **AMPTD Y Scale, Ref Level, (rotate front-panel knob).** |
| 8    | Set the analyzer in zero span to make time-domain measurements | a. Press **SPAN X Scale, Zero Span**  
b. Press **Sweep/Control, Sweep Time, 5, ms** |
| 9    | Use the video trigger to stabilize the trace. | a. Press **Trigger, Video.**  
Since the modulation is a steady tone, you can use video trigger to trigger the analyzer sweep on the waveform and stabilize the trace, much like an oscilloscope. See **Figure 10-1**  
If the trigger level is set too high or too low when video trigger mode is activated, the sweep stops. You need to adjust the trigger level up or down with the front-panel knob until the sweep begins again. |
| 10   | Measure the AM rate using delta markers. | a. Press **Peak Search, Marker Delta, Next Right or Next Left.**  
Use markers and delta markers to measure the AM rate. Place the marker on a peak and then use a delta marker to measure the time difference between the peaks (this is the AM rate of the signal) |
Demodulating AM Signals

Measuring the Modulation Rate of an AM Signal

NOTE Make sure the delta markers above are placed on adjacent peaks. See Figure 10-1 The frequency or the AM rate is 1 divided by the time between adjacent peaks:

\[ \text{AM Rate} = \frac{1}{1.0 \text{ ms}} = 1 \text{ kHz} \]

The signal analyzer can also make this rate calculation by changing the marker readout to inverse time.

Press Marker, Properties, X Axis Scale, Inverse Time.
Another way to calculate the modulation rate would be to view the signal in the frequency domain and measure the delta frequency between the peak of the carrier and the first sideband.
### Measuring the Modulation Index of an AM Signal

This procedure demonstrates how to use the signal analyzer as a fixed-tuned (time-domain) receiver to measure the modulation index as a percent AM value of an AM signal.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 1    | Setup the signal source. | a. Set the source frequency to 300 MHz.

11 IQ Analyzer Measurement
Capturing wideband signals for further analysis

This section demonstrates how to capture complex time domain data from wide bandwidth RF signals. This mode preserves the instantaneous vector relationships of time, frequency, phase and amplitude contained within the selected digitizer span or analysis BW, at the analyzer’s center frequency, for output as IQ data. This IQ data can then be utilized internally or output over LAN, USB or GPIB for use with external analysis tools. Each measurement description specifies the types of data available remotely for that measurement.

The standard 10 MHz Analysis BW and optional 25 MHz Analysis BW digitizers used to capture the wide bandwidth RF signals can be accessed from the front panel in IQ Analyzer (Basic) mode. This IQ Analyzer mode provides basic setup, RF (FFT based) and IQ analysis tools.

Within the IQ Analyzer mode, basic frequency domain, time domain and IQ measurements are available as initial signal and data verification tools in preparation for deriving the IQ data output.

The Complex Spectrum measurement provides a display in the upper window of power versus frequency with current (yellow trace) and average (blue trace) data. In addition, an IQ waveform of voltage versus time is provided in the lower window.

The IQ Waveform measurement provides a time domain view of the RF signal envelope with power versus time or an IQ waveform of voltage versus time.
Complex Spectrum Measurement

This section explains how to make a waveform (time domain) measurement on a W-CDMA signal. (A signal generator is used to simulate a base station.) The measurement of I and Q modulated waveforms in the time domain disclose the voltages which comprise the complex modulated waveform of a digital signal.

NOTE
A display with both an FFT derived spectrum in the upper window and an IQ Waveform in the lower window will appear when you activate a Complex Spectrum measurement. The active window is outlined in green. Changes to Frequency, Span or Amplitude will affect only the active window. Use the Next Window key to select a different window, and Zoom key to enlarge the window.
IQ Waveform (Time Domain) Measurement

This section explains how to make a waveform (time domain) measurement on a W-CDMA signal. (A signal generator is used to simulate a base station.) The measurement of I and Q modulated waveforms in the time domain disclose the voltages which comprise the complex modulated waveform of a digital signal.

The Baseband I/Q functionality is a hardware option, Option BBA. If the option is not installed in the instrument, the I/Q functionality cannot be enabled.

The Baseband I/Q option provides four input ports and one Calibration Output port. The input ports are I, I-bar, Q, and Q-bar. The I and I-bar together compose the I channel and the Q and Q-bar together compose the Q channel. Each channel has two modes of operation:

<table>

13 Concepts
Resolving Closely Spaced Signals

Resolving Signals of Equal Amplitude

Two equal-amplitude input signals that are close in frequency can appear as a single signal trace on the analyzer display. Responding to a single-frequency signal, a swept-tuned analyzer traces out the shape of the selected internal IF (intermediate frequency) filter (typically referred to as the resolution bandwidth or RBW filter). As you change the filter bandwidth, you change the width of the displayed response. If a wide filter is used and two equal-amplitude input signals are close enough in frequency, then the two signals will appear as one signal. If a narrow enough filter is used, the two input signals can be discriminated and appear as separate peaks. Thus, signal resolution is determined by the IF filters inside the analyzer.

The bandwidth of the IF filter tells us how close together equal amplitude signals can be and still be distinguished from each other. The resolution bandwidth function selects an IF filter setting for a measurement. Typically, resolution bandwidth is defined as the 3 dB bandwidth of the filter. However, resolution bandwidth may also be defined as the 6 dB or impulse bandwidth of the filter.

Generally, to resolve two signals of equal amplitude, the resolution bandwidth must be less than or equal to the frequency separation of the two signals. If the bandwidth is equal to the separation and the video bandwidth is less than the resolution bandwidth, a dip of approximately 3 dB is seen between the peaks of the two equal signals, and it is clear that more than one signal is present.

For Signal Analyzers in swept mode, sweep time is automatically set to a value that is inversely proportional to the square of the resolution bandwidth (1/BW^2), to keep the analyzer measurement calibrated. So, if the resolution bandwidth is reduced by a factor of 10, the sweep time is increased by a factor of 100 when sweep time and bandwidth settings are coupled. For the shortest measurement times, use the widest resolution bandwidth that still permits discrimination of all desired signals. Sweep time is also a function of which detector is in use, peak and normal detectors sweep as fast or more quickly than sample or average detectors. The analyzer allows RBW selections up to 8 MHz in 1, 3, 10 steps and it has the flexibility to fine tune RBWs in increments of 10% for a total of 160 RBW settings.

For best sweep times and keeping the analyzer calibrated set the sweep time (Sweep/Control, Sweep Time) to Auto, and the sweep type (Sweep/Control, Sweep Setup, Sweep Type) to Auto. Use the widest resolution bandwidth and the narrowest span that still permits resolution of all desired signals.

Resolving Small Signals Hidden by Large Signals

When dealing with the resolution of signals that are close together and not equal in amplitude, you must consider the shape of the IF filter of the analyzer, as well as its 3 dB bandwidth. (See “Resolving Signals of Equal Amplitude” on page 158 for more information.) The shape of a filter is defined by the selectivity, which is the ratio of the 60 dB bandwidth to the 3 dB bandwidth. If a small signal is too close to a larger signal, the smaller signal can be hidden by the skirt of the larger signal.
To view the smaller signal, select a resolution bandwidth such that $k$ is less than $a$ (see Figure 13-1). The separation between the two signals ($a$) must be greater than half the filter width of the larger signal ($k$), measured at the amplitude level of the smaller signal.

The digital filters in the analyzer have filter widths about one-third as wide as typical analog RBW filters. This enables you to resolve close signals with a wider RBW (for a faster sweep time).

*Figure 13-1  RBW Requirements for Resolving Small Signals*
Trigger Concepts

NOTE  The trigger functions let you select the trigger settings for a sweep or measurement. When using a trigger source other than Free Run, the analyzer will begin a sweep only with the selected trigger conditions are met. A trigger event is defined as the point at which your trigger source signal meets the specified trigger level and polarity requirements (if any). In FFT measurements, the trigger controls when the data is acquired for FFT conversion.

Selecting a Trigger

1. **Free Run Triggering**
   
   Pressing this key, when it is not selected, selects free-run triggering. Free run triggering occurs immediately after the sweep/measurement is initiated.
   
   Press **Trigger, Free Run**

2. **Video Triggering**
   
   The Video trigger condition is met when the video signal (the filtered and detected version of the input signal, including both RBW and VBW filtering) crosses the video trigger level. Video triggering triggers the measurement at the point at which the rising signal crosses the video trigger horizontal green line on the display:
   
   Press **Trigger, Video, Video, Trigger Level, −30, dBm**. (If Video trigger has not already been selected, you need to press Video a second time to get to the Trigger Level function.)

3. **External Triggering**
   
   In the event that you have an external trigger available that can be used to synchronize with the burst of interest, connect the trigger signal to the rear of the analyzer using either the **Trigger 1 In** or **Trigger 2 In** input connector. It might be necessary to adjust the trigger level by rotating the front panel knob or by entering the numeric value on the keypad.
   
   Press **Trigger, External 1** or **External 2, Trigger Level**, and adjust as necessary.

4. **RF Burst Wideband Triggering**
   
   RF burst triggering occurs in the IF circuitry chain, as opposed to after the video detection circuitry with video triggering. In the event video triggering is used, the detection filters are limited to the maximum width of the resolution bandwidth filters. Set the analyzer in RF burst trigger mode.
   
   Press **Trigger, RF Burst**.

5. **Line Triggering**
Line triggering selects the line signal as the trigger. A new sweep/measurement will start synchronized with the next cycle of the line voltage. Pressing this key, when it is already selected, access the line trigger setup menu.

Press **Trigger, Line**.

6. **Periodic Timer Triggering**

This feature selects the internal periodic timer signal as the trigger. Trigger occurrences are set by the **Periodic Timer** parameter, which is modified by the **Sync Source** and **Offset**. Figure 13-2 shows the action of the periodic timer trigger. Before reviewing the figure, we'll explain some uses for the periodic trigger.

A common application is measuring periodic burst RF signals for which a trigger signal is not easily available. For example, we might be measuring a TDMA radio which bursts every 20 ms. Let's assume that the 20 ms period is very consistent. Let's also assume that we do not have an external trigger source available that is synchronized with the period, and that the signal-to-noise ratio of the signal is not high enough to provide a clean RF burst trigger at all of the analysis frequencies. For example, we might want to measure spurious transmissions at an offset from the carrier that is larger than the bandwidth of the RF burst trigger. In this application, we can set the **Periodic Timer** to a 20.00 ms period and adjust the offset from that timer to position our trigger just where we want it. If we find that the 20.00 ms is not exactly right, we can adjust the period slightly to minimize the drift between the period timer and the signal to be measured.

A second way to use this feature would be to use **Sync Source** temporarily, instead of **Offset**. In this case, we might tune to the signal in a narrow span and use the **RF Burst** trigger to synchronize the periodic timer. Then we would turn the sync source off so that it would not mistrigger. Mistriggering can occur when we are tuned so far away from the RF burst trigger that it is no longer reliable.

A third example would be to synchronize to a signal that has a reference time element of much longer period than the period of interest. In some CDMA applications, it is useful to look at signals with a short periodicity, by synchronizing that periodicity to the “even-second clock” edge that happens every two seconds. Thus, we could connect the even-second clock trigger to Ext1 and use then Ext1 as the sync source for the periodic timer.

The figure below illustrates this third example. The top trace represents the even-second clock. It causes the periodic timer to synchronize with the leading edge shown. The analyzer trigger occurs at a time delayed by the accumulated offset from the period trigger event. The periodic timer continues to run, and triggers continue to occur, with a periodicity determined by the analyzer time base. The timer output (labeled “late event”) will drift away from its ideal time due to imperfect matching between the time base of the signal being measured and the time base of the analyzer, and also because of imperfect setting of the period parameter. But the synchronization is restored on the next even-second clock event. (“Accumulated offset” is described in the in the **Offset** function section.)
Figure 13-2  Frame Triggering

a. **Period**

Sets the period of the internal periodic timer clock. For digital communications signals, this is usually set to the frame period of your current input signal. In the case that sync source is not set to OFF, and the external sync source rate is changed for some reason, the periodic timer is synchronized at the every external synchronization pulse by resetting the internal state of the timer circuit.

Press **Trigger, Periodic Timer**.

b. **Offset**

Adjusts the accumulated offset between the periodic timer events and the trigger event. Adjusting the accumulated offset is different than setting an offset, and requires explanation.

The periodic timer is usually unsynchronized with any external events, so the timing of its output events has no absolute meaning. Since the timing relative to external events (RF signals) is important, you need to be able to adjust (offset) it. However, you have no direct way to see when the periodic timer events occur. All that you can see is the trigger timing. When you want to adjust the trigger timing, you will be changing the internal offset between the periodic timer events and the trigger event. Because the absolute value of that internal offset is unknown, we will just call that the accumulated offset. Whenever the **Offset** parameter is changed, you are changing that accumulated offset. You can reset the displayed offset using **Reset Offset Display**. Changing the display does not change the value of the accumulated offset, and you can still make additional changes to accumulated offset.

Press **Trigger, Periodic Timer**.

c. **Reset Offset Display**

Resets the value of the periodic trigger offset display setting to 0.0 seconds. The current displayed trigger location may include an offset value defined with the **Offset** key. Pressing this key redefines the currently displayed trigger location as the new trigger point that is 0.0 s offset. The **Offset** key can then be used to add offset relative to this new timing.
Press **Trigger, Periodic Timer**.
Time Gating Concepts

Introduction: Using Time Gating on a Simplified Digital Radio Signal

This section shows you the concepts of using time gating on a simplified digital radio signal. The section on Making Time-Gated Measurements demonstrates time gating examples.

Figure 13-3 shows a signal with two radios, radio 1 and radio 2, that are time-sharing a single frequency channel. Radio 1 transmits for 1 ms then radio 2 transmits for 1 ms.

We want to measure the unique frequency spectrum of each transmitter.

A signal analyzer without time gating cannot do this. By the time the signal analyzer has completed its measurement sweep, which lasts about 50 ms, the radio transmissions switch back and forth 25 times. Because the radios are both transmitting at the same frequency, their frequency spectra overlap, as shown in Figure 13-4. The signal analyzer shows the combined spectrum; you cannot tell which part of the spectrum results from which signal.

Time gating allows you to see the separate spectrum of radio 1 or radio 2 to determine the source of the spurious signal, as shown in Figure 13-5.
Time gating lets you define a time window (or time gate) of when a measurement is performed. This lets you specify the part of a signal that you want to measure, and exclude or mask other signals that might interfere.
How Time Gating Works

Time gating is achieved by the signal analyzer selectively interrupting the path of the detected signal, with a gate, as shown in Figure 13-9 and Figure 13-8. The gate determines the times at which it captures measurement data (when the gate is turned “on,” under the Gate menu, the signal is being passed, otherwise when the gate is “off,” the signal is being blocked). Under the right conditions, the only signals that the analyzer measures are those present at the input to the analyzer when the gate is on. With the correct signal analyzer settings, all other signals are masked out.

There are typically two main types of gating conditions, edge and level:

- With edge gating, the gate timing is controlled by user parameters (gate delay and gate length) following the selected (rising or falling) edge of the trigger signal. The gate passes a signal on the edge of the trigger signal (after the gate delay time has been met) and blocks the signal at the end of the gate length.

  With edge gating, the gate control signal is usually an external periodic TTL signal that rises and falls in synchronization with the rise and fall of the pulsed radio signal. The gate delay is the time the analyzer waits after the trigger event to enable the gate (see Figure 13-7).

- With level gating, the gate will pass a signal when the gate signal meets the specified level (high or low). The gate blocks the signal when the level conditions are no longer satisfied (level gating does not use gate length or gate delay parameters).

Figure 13-7   Edge Trigger Timing Relationships

With Agilent signal analyzers, there are three different implementations for time gating: gated LO, gated video and gated FFT.
Gated Video Concepts

Gated video may be thought of as a simple gate switch, which connects the signal to the input of the signal analyzer. When the gate is “on” (under the Gate menu) the gate is passing a signal. When the gate is “off,” the gate is blocking the signal. Whenever the gate is passing a signal, the analyzer sees the signal. In Figure 13-8 notice that the gate is placed after the envelope detector and before the video bandwidth filter in the IF path (hence “gated video”).

The RF section of the signal analyzer responds to the signal. The selective gating occurs before the video processing. This means that there are some limitations on the gate settings because of signal response times in the RF signal path.

With video gating the analyzer is continually sweeping, independent of the position and length of the gate. The analyzer must be swept at a minimum sweep time (see the sweep time calculations later in this chapter) to capture the signal when the gate is passing a signal. Because of this, video gating is typically slower than gated LO and gated FFT.

Figure 13-8  
Gated Video Signal Analyzer Block Diagram

Gated LO Concepts

Gated LO is a very sophisticated type of time gating that sweeps the LO only while the gate is “on” and the gate is passing a signal. See Figure 13-9 for a simplified block diagram of gated LO operation. Notice that the gate control signal controls when the scan generator is sweeping and when the gate passes or blocks a signal. This allows the analyzer to sweep only during the periods when the gate passes a signal. Gated LO is faster than Gated Video because Gated Video must constrain sweep time so that each point is long enough to include a burst event. On the other hand, when in Gated LO, multiple points may be swept during each gate.
Gated FFT Concepts

Gated FFT (Fast-Fourier Transform) is an FFT measurement which begins when the trigger conditions are satisfied.

The process of making a spectrum measurement with FFTs is inherently a “gated” process, in that the spectrum is computed from a time record of short duration, much like a gate signal in swept-gated analysis.

Using the analyzer in FFT mode, the duration of the time record to be gated is:

\[
\text{FFT Time Record (to be gated)} = \frac{1.83}{\text{RBW}}
\]

The duration of the time record is within a tolerance of approximately 3% for resolution bandwidths up through 1 MHz. Unlike swept gated analysis, the duration of the analysis in gated FFT is fixed by the RBW, not by the gate signal. Because FFT analysis is faster than swept analysis (up to 7.99 MHz), the gated FFT measurements can have better frequency resolution (a narrower RBW) than swept analysis for a given duration of the signal to be analyzed.
Time Gating Basics (Gated LO and Gated Video)

The gate passes or blocks a signal with the following conditions:

- **Trigger condition** - Usually an external transistor-transistor logic (TTL) periodic signal for edge triggering and a high/low TTL signal for level triggering.

- **Gate delay** - The time after the trigger condition is met when the gate begins to pass a signal.

- **Gate length** - The gate length setting determines the length of time a gate begins to pass a signal.

To understand time gating better, consider a spectrum measurement performed on two pulsed-RF signals sharing the same frequency spectrum. You will need to consider the timing interaction of three signals with this example:

- The composite of the two pulsed-RF signals.
- The gate trigger signal (a periodic TTL level signal).
• The gate signal. This TTL signal is low when the gate is “off” (blocking) and high when the gate is “on” (passing).

The timing interactions between the three signals are best understood if you observe them in the time domain (see Figure 13-11).

The main goal is to measure the spectrum of signal 1 and determine if it has any low-level modulation or spurious signals.

Because the pulse trains of signal 1 and signal 2 have almost the same carrier frequency, their spectra overlap. Signal 2 will dominate in the frequency domain due to its greater amplitude. Without gating, you won’t see the spectrum of signal 1; it is masked by signal 2.

To measure signal 1, the gate must be on only during the pulses from signal 1. The gate will be off at all other times, thus excluding all other signals. To position the gate, set the gate delay and gate length, as shown in Figure 13-11, so that the gate is on only during some central part of the pulse. Carefully avoid positioning the gate over the rising or falling pulse edges. When gating is activated, the gate output signal will indicate actual gate position in time, as shown in the line labeled “Gate.”

Once the signal analyzer is set up to perform the gate measurement, the spectrum of signal 1 is visible and the spectrum of signal 2 is excluded, as shown if Figure 13-13 In addition, when viewing signal 1, you also will have eliminated the pulse spectrum generated from the pulse edges. Gating has allowed you to view spectral components that otherwise would be hidden.
Moving the gate so that it is positioned over the middle of signal 2 produces a result as shown in Figure 13-15. Here, you see only the spectrum within the pulses of signal 2; signal 1 is excluded.
Measuring a Complex/Unknown Signal

NOTE

The steps below help to determine the signal analyzer settings when using time gating. The steps apply to the time gating approaches using gated LO and gated video.

This example shows you how to use time gating to measure a very specific signal. Most signals requiring time gating are fairly complex and in some cases extra steps may be required to perform a measurement.

**Step 1.** Determine how your signal under test appears in the time domain and how it is synchronized to the trigger signal.

You need to do this to position the time gate by setting the delay relative to the trigger signal. To set the delay, you need to know the timing relationship between the trigger and the signal under test. Unless you already have a good idea of how the two signals look in the time domain, you can examine the signals with an oscilloscope to determine the following parameters:

- Trigger type (edge or level triggering)
- Pulse repetition interval (PRI), which is the length of time between trigger events (the trigger period).
- Pulse width, or \( \tau \)
- Signal delay (SD), which is the length of time occurring between the trigger event and when the signal is present and stable. If your trigger occurs at the same time as the signal, signal delay will be zero.
In Figure 13-16, the parameters are:

- Pulse repetition interval (PRI) is 5 ms.
- Pulse width (τ) is 3 ms.
- Signal delay (SD) is 1 ms for positive edge trigger (0.6 ms for negative edge trigger).
- Gate delay (D) is 2.5 ms.
- Setup time (SUT) is 1.5 ms.

**Step 2.** Set the signal analyzer sweep time:

**Gated LO:** Sweep time does not affect the results of gated LO unless the sweep time is set too fast. In the event the sweep time is set too fast, Meas Uncal appears on the screen and the sweep time will need to be increased.

**Gated Video:** Sweep time does affect the results from gated video. The sweep time must be set accordingly for correct time gating results. The recommended sweep time is at least the number of sweep points – 1 multiplied by the PRI (pulse repetition interval). Measurements can be made with sweep times as fast as (sweep points–1)*(PRI–τ).

**Step 3.** Locate the signal under test on the display of the signal analyzer. Set the center frequency and span to view the signal characteristics that you are interested in measuring. Although the analyzer is not yet configured for correct gated measurements, you will want to determine the approximate frequency and span in which to display the signal of interest. If the signal is erratic or intermittent, you may want to hold the maximum value of the signal with Max Hold (located under the Trace/Detector menu) to determine the frequency of peak energy.
To optimize measurement speed in the Gated LO case, set the span narrow enough so that the display will still show the signal characteristics you want to measure. For example, if you wanted to look for spurious signals within a 200 kHz frequency range, you might set the frequency span to just over 200 kHz.

**Step 4.** Determine the setup time and signal delay to set up the gate signal. Turn on the gate and adjust the gate parameters including gate delay and gate length as shown below.

Generally, the gate should be positioned over a part of the signal that is stable, not over a pulse edge or other transition that might disturb the spectrum. Starting the gate at the center of the pulse gives a setup time of about half the pulse width. Setup time describes the length of time during which that signal is present and stable before the gate comes on. The setup time (SUT) must be long enough for the RBW filters to settle following the burst-on transients. Signal delay (SD) is the length of time after the trigger, but before the signal of interest occurs and becomes stable. If the trigger occurs simultaneously with the signal of interest, SD is equal to zero, and SUT is equal to the gate delay. Otherwise, SUT is equal to the gate delay minus SD. See Figure 13-17.

**Figure 13-17 Positioning the Gate**

There is flexibility in positioning the gate, but some positions offer a wider choice of resolution bandwidths. A good rule of thumb is to position the gate from 20% to 90% of the burst width. Doing so provides a reasonable compromise between setup time and gate length.

**Figure 13-18 Best Position for Gate**
As a general rule, you will obtain the best measurement results if you position the gate relatively late within the signal of interest, but without extending the gate over the trailing pulse edge or signal transition. Doing so maximizes setup time and provides the resolution bandwidth filters of the signal analyzer the most time to settle before a gated measurement is made. “Relatively late,” in this case, means allowing a setup time of at least 3.84/resolution bandwidth (see step 5 for RBW calculations).

As an example, if you want to use a 1 kHz resolution bandwidth for measurements, you will need to allow a setup time of at least 3.84 ms.

Note that the signal need not be an RF pulse. It could be simply a particular period of modulation in a signal that is continuously operating at full power, or it could even be during the off time between pulses. Depending on your specific application, adjust the gate position to allow for progressively longer setup times (ensuring that the gate is not left on over another signal change such as a pulse edge or transient), and select the gate delay and length that offer the best representation of the signal characteristics of interest on the display.

If you were measuring the spectrum occurring between pulses, you should use the same (or longer) setup time after the pulse goes away, but before the gate goes on. This lets the resolution bandwidth filters fully discharge the large pulse before the measurement is made on the low-level interpulse signal.

**Figure 13-19 Setup Time for Interpulse Measurement**

Step 5. The resolution bandwidth will need to be adjusted for gated LO and gated video. The video bandwidth will only need to be adjusted for gated video.

**Resolution Bandwidth:**

The resolution bandwidth you can choose is determined by the gate position, so you can trade off longer setup times for narrower resolution bandwidths. This trade-off is due to the time required for the resolution-bandwidth filters to fully charge before the gate comes on. Setup time, as mentioned, is the length of time that the signal is present and stable before the gate comes on.
Because the resolution-bandwidth filters are band-limited devices, they require a finite amount of time to react to changing conditions. Specifically, the filters take time to charge fully after the analyzer is exposed to a pulsed signal.

Because setup time should be greater than filter charge times, be sure that:

\[
SUT > \frac{3.84}{RBW}
\]

where SUT is the same as the gate delay in this example. In this example with SUT equal to 1.5 ms, RBW is greater than 2.56 kHz; that is, RBW is greater than 1333 Hz. The resolution bandwidth should be set to the next larger value, 2.7 kHz.

**Video Bandwidth:**

For gated LO measurements the VBW filter acts as a track-and-hold between sweep times. With this behavior, the VBW does not need to resettle on each restart of the sweep.

**Step 6.** Adjust span as necessary, and perform your measurement.

The analyzer is set up to perform accurate measurements. Freeze the trace data by activating single sweep, or by placing your active trace in view mode. Use the markers to measure the signal parameters you chose in step 1. If necessary, adjust span, but do not decrease resolution bandwidth, video bandwidth, or sweep time.
"Quick Rules" for Making Time-Gated Measurements

This section summarizes the rules described in the previous sections.

Table 13-1
Determining Signal Analyzer Settings for Viewing a Pulsed RF Signal

<table>
<thead>
<tr>
<th>Signal Analyzer Function</th>
<th>Signal Analyzer Setting</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sweep Time (gated video only)</td>
<td>Set the sweep time to be equal to or greater than (number of sweep points - 1) × pulse repetition interval (PRI):</td>
<td>Because the gate must be on at least once per trace point, the sweep time should be set such that the sweep time for each trace point is greater than or equal to the pulse repetition interval.</td>
</tr>
<tr>
<td>Gate Delay</td>
<td>The gate delay is equal to the signal delay plus one-fourth the pulse width: Gate Delay = Signal Delay + τ/5</td>
<td>The gate delay must be set so that the gating captures the pulse. If the gate delay is too short or too long, the gating can miss the pulse or include resolution bandwidth transient responses.</td>
</tr>
<tr>
<td>Gate Length</td>
<td>The gate length minimum is equal to one-fourth the pulse width (maximum about one-half): Gate Length = 0.7 x τ/4</td>
<td>If the gate length is too long, the signal display can include transients caused by the signal analyzer filters. The recommendation for gate placement can be between 20 % to 90 % of the pulse width.</td>
</tr>
<tr>
<td>Resolution Bandwidth</td>
<td>Set the resolution bandwidth: RBW &gt; 19.5/τ</td>
<td>The resolution bandwidth must be wide enough so that the charging time for the resolution bandwidth filters is less than the pulse width of the signal.</td>
</tr>
</tbody>
</table>
Most control settings are determined by two key parameters of the signal under test: the pulse repetition interval (PRI) and the pulse width (τ). If you know these parameters, you can begin by picking some standard settings. Table 13-2 summarizes the parameters for a signal whose trigger event occurs at the same time as the beginning of the pulse (in other words, SD is 0). If your signal has a non-zero delay, just add it to the recommended gate delay.

<td>Widen resolution bandwidth or video bandwidth, or both.</td>
</tr>
</tbody>
</table>
Using the Edge Mode or Level Mode for Triggering

Depending on the trigger signal that you are working with, you can trigger the gate in one of two separate modes: edge or level. This gate-trigger function is separate from the normal external trigger capability of the signal analyzer, which initiates a sweep of a measurement trace based on an external signal.

**Edge Mode**

Edge mode lets you position the gate relative to either the rising or falling edge of a trigger signal. The left diagram of Figure 13-22 shows triggering on the positive edge of the trigger signal while the right diagram shows negative edge triggering.

Example of key presses to initiate positive edge triggering:
Press **Sweep, Gate, More, Polarity** (Pos).

*Figure 13-22 Using Positive or Negative Edge Triggering*

**Level Mode**

In level gate-control mode, an external trigger signal opens and closes the gate. Either the TTL high level or TTL low level opens the gate, depending on the setting of **Trig Slope**. Gate delay affects the start of the gate but not the end. Gate length is applicable when using level mode triggering. Level mode is useful when your trigger signal occurs at exactly the same time as does the portion of the signal you want to measure.
Noise Measurements Using Time Gating

Time gating can be used to measure many types of signals. Noise and noise-like signals are often a special case in spectrum analysis. With the history of gated measurements, these signals are especially noteworthy.

The average detector is the best detector to use for measuring noise-like signals because it uses all the available noise power all the time in its measurement. The sample detector is also a good choice because it, too, is free from the peak biases of the peak detector, normal and negative peak detectors.

When using the average or sample detector, noise density measurements using the noise marker or band/interval density marker can be made without any consideration of the use of gating--gated measurements work just as well as non-gated measurements. Thus, the average detector is recommended for noise density measurements.

Older analyzers only had the gated video version of gating available, and these only worked with the peak detector, so the rest of this section will discuss the trade-offs associated with trying to replicate these measurements with an X-Series analyzer.

Unlike older analyzers, X-Series analyzers can make competent measurements of noise density using the noise marker with all detectors, not just those that are ideal for noise measurements. Thus, X-Series analyzers can make noise density measurements with peak detection, compensating for the extent to which peak detection increases the average response of the analyzer to noise. When comparing a gated video measurement using the noise marker between an X-Series and an older analyzer where both use the peak detector, the X-Series answer will be approximately correct, while the older analyzer will need a correction factor. That correction factor is discussed in Agilent Technologies Application Note 1303, Spectrum Analyzer Measurements and Noise, in the section on Peak-detected Noise and TDMA ACP Measurements.

When making measurements of Band/Interval Power or Band/Interval Density, the analyzer does not make compensations for peak detection. For best measurements with these marker functions, average or sample detection should be used.
AM and FM Demodulation Concepts

Demodulating an AM Signal Using the Analyzer as a Fixed Tuned Receiver (Time-Domain)

The zero span mode can be used to recover amplitude modulation on a carrier signal.

The following functions establish a clear display of the waveform:

• Triggering stabilizes the waveform trace by triggering on the modulation envelope. If the modulation of the signal is stable, video trigger synchronizes the sweep with the demodulated waveform.
• Linear display mode should be used in amplitude modulation (AM) measurements to avoid distortion caused by the logarithmic amplifier when demodulating signals.
• Sweep time to view the rate of the AM signal.
• RBW and VBW are selected according to the signal bandwidth.

Demodulating an FM Signal Using the Analyzer as a Fixed Tuned Receiver (Time-Domain)

To recover the frequency modulated signal, a spectrum analyzer can be used as a manually tuned receiver (zero span). However, in contrast to AM, the signal is not tuned into the passband center, but to one slope of the filter curve as Figure 13-23

Figure 13-23 Determining FM Parameters using FM to AM Conversion

Here the frequency variations of the FM signal are converted into amplitude variations (FM to AM conversion) utilizing the slope of the selected bandwidth filter. The reason we want to measure the AM component is that the envelope detector responds only to AM variations. There are no changes in amplitude if the frequency changes of the FM signal are limited to the flat part of the RBW (IF filter). The resultant AM signal is then detected with the envelope detector and displayed in the time domain.
IQ Analysis Concepts

Purpose

IQ Analysis (Basic) mode is used to capture complex time domain data from wide bandwidth RF signals. This mode preserves the instantaneous vector relationships of time, frequency, phase and amplitude contained within the selected digitizer span or analysis BW, at the analyzer’s center frequency, for output as IQ data. This IQ data can then be utilized internally or output over LAN, USB or GPIB for use with external analysis tools. Each measurement description specifies the types of data available remotely for that measurement.

Within the IQ Analyzer mode, basic frequency domain, time domain and IQ measurements are available as initial signal and data verification tools in preparation for deriving the IQ data output. This is accomplished using the Complex Spectrum and IQ Waveform measurements. Although Complex Spectrum and IQ Waveform are defined as measurements in the IQ Analyzer (Basic) mode, they act primarily as tools to verify the signals and data as stated above.

Complex Spectrum Measurement

Purpose

This measurement is FFT (Fast Fourier Transform) based. The FFT-specific parameters are located in the Advanced menu. The Complex Spectrum measurement provides a display in the upper window of power versus frequency with current (yellow trace) and average (blue trace) data. In addition, an IQ waveform of voltage versus time is provided in the lower window. One advantage of having an I/Q view available while in the spectrum measurement is that it allows you to view complex components of the same signal without changing settings or measurements.

Measurement Method

The measurement uses digital signal processing to sample the input signal and convert it to the frequency domain. With the instrument tuned to a fixed center frequency, samples are digitized at a high rate, converted to I and Q components with DSP hardware, and then converted to the frequency domain with FFT software.

Troubleshooting Hints

Changes made by the user to advanced spectrum settings, particularly to ADC range settings, can inadvertently result in spectrum measurements that are invalid and cause error messages to appear. Care needs to be taken when using advanced features.

IQ Waveform Measurement

Purpose

The IQ Waveform measurement provides a time domain view of the RF signal envelope with power versus time or an IQ waveform with the I and Q signal waveforms in parameters of voltage versus time. The RF Envelope view provides the power versus
time display, and the I/Q Waveform view provides the voltage versus time display. One advantage of having an I/Q Waveform view available while making a waveform measurement is that it allows you to view complex components of the same signal without changing settings or measurements.

The waveform measurement can be used to perform general purpose power measurements in the time domain with excellent accuracy.

**Measurement Method**

The instrument makes repeated power measurements at a set frequency, similar to the way a swept-tuned signal analyzer makes zero span measurements. The input analog signal is converted to a digital signal, which then is processed into a representation of a waveform measurement. The measurement relies on a high rate of sampling to create an accurate representation of a time domain signal.
Spurious Emissions Measurement Concepts

Purpose

Spurious signals can be caused by different combinations of signals in the transmitter. The spurious emissions from the transmitter should be minimized to guarantee minimum interference with other frequency channels in the system. Harmonics are distortion products caused by nonlinear behavior in the transmitter. They are integer multiples of the transmitted signal carrier frequency.

This measurement verifies the frequency ranges of interest are free of interference by measuring the spurious signals specified by the user defined range table.

Measurement Method

The table-driven measurement has the flexibility to set up custom parameters such as frequency, span, resolution bandwidth, and video bandwidth. Up to the top 40 spurs can be viewed

For each range that you specify and activate, the analyzer scans the band using the specified Range Table settings. Then using the Peak Excursion and Peak Threshold values determines which spurs to report.

As each band is swept, any signal which is above the Peak Threshold value and has a peak excursion of greater than the Peak Excursion value will be added to a list of spurs displayed in the lower results window. A total of 200 spurs can be recorded for one measurement, with a limit of 10 spurs per frequency range. To improve repeatability, you can increase the number of averages.

From the spurs in the list, those with peak amplitude greater than the Absolute Limit for that range will be logged as a measurement failure and denoted by an 'F' in the 'Amplitude' column of the table. If no spurs are reported, but the measured trace exceeds the limit line for any range, the fail flag is set to fail.

This measurement has the ability to display two traces using different detectors on the display simultaneously. All spur detection and limit line testing are only applied to the trace associated with Detector 1, which will be colored yellow. The trace associated with Detector 2 will be colored cyan.

If the sweep time for the range exceeds 2 seconds, a flashing message “Sweeping...Please Wait” will appear in the annunciator area. This advises you that the time to complete the sweep is between 2 and 2000 seconds, and is used as without it the display would appear stagnant and you may think the measurement is not functional.
Spectrum Emission Mask Measurement Concepts

Purpose

The Spectrum Emission Mask measurement includes the in-band and out-of-band spurious emissions. As it applies to W-CDMA (3GPP), this is the power contained in a specified frequency bandwidth at certain offsets relative to the total carrier power. It may also be expressed as a ratio of power spectral densities between the carrier and the specified offset frequency band.

This spectrum emission mask measurement is a composite measurement of out-of-channel emissions, combining both in-band and out-of-band specifications. It provides useful figures-of-merit for the spectral regrowth and emissions produced by components and circuit blocks, without the rigor of performing a full spectrum emissions mask measurement.

Measurement Method

The spectrum emission mask measurement measures spurious signal levels in up to five pairs of offset/region frequencies and relates them to the carrier power. The reference channel integration bandwidth method is used to measure the carrier channel power and offset/region powers. When Offset is selected, spectrum emission mask measurements are made, relative to the carrier channel frequency bandwidth. When Region is selected, spurious emission absolute measurements are made, set by specifying start and stop RF frequencies. The upper frequency range limit is 3.678 GHz.

This integration bandwidth method is used to perform a data acquisition. In this process, the reference channel integration bandwidth (Meas BW) is analyzed using the automatically defined resolution bandwidth (Res BW), which is much narrower than the channel bandwidth. The measurement computes an average power of the channel or offset/region over a specified number of data acquisitions, automatically compensating for resolution bandwidth and noise bandwidth.

This measurement requires the user to specify the measurement bandwidths of carrier channel and each of the offset/region frequency pairs up to 5. Each pair may be defined with unique measurement bandwidths. The results are displayed both as relative power in dBc, and as absolute power in dBm.
Occupied Bandwidth Measurement Concepts

Purpose

Occupied bandwidth measures the bandwidth containing 99.0 of the total transmission power.

The spectrum shape of a signal can give useful qualitative insight into transmitter operation. Any distortion to the spectrum shape can indicate problems in transmitter performance.

Measurement Method

The instrument uses digital signal processing (DSP) to sample the input signal and convert it to the frequency domain. With the instrument tuned to a fixed center frequency, samples are digitized at a high rate with DSP hardware, and then converted to the frequency domain with FFT software.

The total absolute power within the measurement frequency span is integrated for its 100% of power. The lower and upper frequencies containing 0.5% each of the total power are then calculated to get 99.0% bandwidth.
Baseband I/Q Inputs (Option BBA) Measurement Concepts

The N9020A Option BBA Baseband I/Q Inputs provides the ability to analyze baseband I/Q signal characteristics of mobile and base station transmitters. This option may be used only in conjunction with the following modes:

- IQ Analyzer (Basic)
- 802.16 OFDMA (WiMAX/WiBro)
- cdma2000
- GSM/EDGE
- TD-SCDMA

What are Baseband I/Q Inputs?

Option BBA consists of a Baseband Input module, four input connectors, and a calibration output connector. The connectors are at the left side of the front panel. The two ports labeled “I” and “Q” are the “unbalanced” inputs.

An unbalanced or “single-ended” baseband measurement of an I or Q signal is made using a probe connected to the I or Q connector. A simultaneous I/Q unbalanced single-ended measurement may be made using two probes connected to the I and Q input connectors.

If “balanced” signals are available, they may be used to make a more accurate measurement. Balanced signals are signals present in two separate conductors, are symmetrical about ground, and are opposite in polarity, or out of phase by 180 degrees.

Measurements using balanced signals can have a higher signal to noise ratio resulting in improved accuracy. Noise coupled into each conductor equally in a “common mode” to both signals may be separated from the signal. The measure of this separation is “common-mode rejection”.

To make a balanced measurement, the two connectors labeled “I” and “Q” are used in conjunction with the I and Q inputs. The terms “I-bar” and “Q-bar” may be applied to the signals, as well as the inputs themselves. Probes (customer provided) must be used to input balanced baseband I/Q signals. This may be referred to as a balanced measurement.

Balanced baseband measurements are made using the I and connectors for I only signal measurements, while the Q and connectors are used for a Q only signal measurement. Balanced measurements of I/Q require differential probe connections to all four input connectors. For details of probe selection and use, refer to “Selecting Input Probes for Baseband Measurements” on page 190.

What are Baseband I/Q Signals?

In transmitters, the term baseband I/Q refers to signals that are the fundamental products of individual I/Q modulators, before the I and Q component signals are combined, and before upconversion to IF or RF frequencies.
In receivers, baseband I/Q analysis may be used to test the I and Q products of I/Q demodulators, after an RF signal has been downconverted and demodulated.

**Why Make Measurements at Baseband?**

Baseband I/Q measurements are a valuable means of making qualitative analyses of the following operating characteristics:

- I/Q signal layer access for performing format-specific demodulation measurements (for example, CDMA, GSM, W-CDMA).
- Modulation accuracy – that is, I/Q plane metrics:
  - rho
  - error vector magnitude; rms, peak, or 95%
  - carrier feed-through
  - frequency error
  - magnitude and phase errors
- Code-domain analysis (including code-specific metrics)
- CCDF of $I^2 + Q^2$
- Single sideband (SSB) metrics for assessing output quality
- Basic analysis of I and Q signals in isolation including: DC content, rms and peak to peak levels, CCDF of each channel

Comparisons of measurements made at baseband and RF frequencies produced by the same device are especially revealing. Once signal integrity is verified at baseband, impairments can be traced to specific stages of upconversion, amplification, or filtering by RF analysis. In addition, impairments to signal quality that are apparent at RF frequencies may be traceable to baseband using baseband analysis.
Selecting Input Probes for Baseband Measurements

The selection of baseband measurement probe(s) and measurement method is primarily dependent on the location of the measurement point in the circuit. The probe must sample voltages without imposing an inappropriate load on the circuit.

The system supports a variety of 1 MΩ impedance input passive probes as well as the Agilent 1153A active differential probe using the InfiniMax probe interface.

The Agilent 1153A active probe can be used for both single-ended and differential measurements. In either case a single connection is made for each channel (on either the I or Q input). The input is automatically configured to 50 Ω single-ended type measurement and the probe power is supplied through the InfiniMax interface. The probe can be configured for a variety of input coupling and low frequency rejection modes. In addition, a wide range of offset voltages and probe attenuation accessories are supported at the probe interface. The active probe has the advantage that it does not significantly load the circuit under test, even with unity gain probing.

With passive 1 MΩ probes, the probe will introduce a capacitive load on the circuit, unless a higher attenuation is used at the probe interface. Higher attenuation helps isolate the probe, however, it reduces the signal level and degrades the signal-to-noise-ratio of the measurement. Passive probes are available with a variety of attenuation values for a moderate cost. Many Agilent passive probes can be automatically identified by the system, setting the input impedance required as well as the nominal attenuation. For single-ended measurements a single probe is used for each channel. Other passive probes can be used, after manually setting the attenuation and probe impedance configurations.

For full differential measurements, the system supports probes on each of the four inputs. The attenuation for each of the probes should be the same for good common mode rejection and channel match.

Supported Probes

The following table lists the probes currently supported by Option BBA:

<table>

**Baseband I/Q Inputs (Option BBA) Measurement Concepts**

**Probes without Stored Calibration**

The following 115xA active probes may be used with the MXA’s baseband IQ inputs and may use the same probe calibration utility software. However, the probe calibration data is not stored in the MXA and will be lost if power is cycled. Use of the E2655B de-skew and calibration kit, including the calibration fixture, is required because of the different physical configuration of the probes. (The physical connections are different mechanically, not electrically.)

**Baseband I/Q Measurement Views**

Measurement result views made in the IQ Analyzer (Basic) mode are available for baseband signals if they relate to the nature of the signal itself. Many measurements which relate to the characteristics that baseband I and Q signals have when mixed and upconverted to signals in the RF spectrum can be made as well. However, measurements which relate to the characteristics of an upconverted signal that lie beyond the bandwidth available to the Baseband I/Q Input circuits cannot be measured (the limit are dependent on the installed options: Standard – 10 Hz to 20 MHz, Option B25 – 10 Hz to 50 MHz, and Option S40 – 10 Hz to 80 MHz).

At RF frequencies, power measurements are conventionally displayed on a logarithmic vertical scale in dBm units, whereas measurements of baseband signals using Baseband I/Q inputs may be conveniently displayed as voltage using a linear vertical scale as well as a log scale.

**Spectrum Views and 0 Hz Center Frequency**

To view the Spectrum display of I only or Q only signals, use the Complex Spectrum measurement capability in IQ Analyzer (Basic) Mode.

I only and Q only Spectrum views are conventional, displayed with 0 Hz at the left side of the horizontal axis. When upconverted or multiplied, an I only or Q only signal could ultimately lie above or below the carrier center frequency, but in either case it will only occupy half the bandwidth.
**Waveform Signal Envelope Views of I only or Q only**

To view the Signal Envelope display of I only or Q only signals, use the Waveform measurement capability in IQ Analyzer (Basic) Mode.

The I and Q Waveform of an I/Q signal is very different from the complex signal displayed in the RF Envelope view. That is because the RF Envelope is a product of both the I and Q modulation waveforms.

However, an I and Q Waveform measurement of an I only or Q only signal is exactly the same signal displayed in the RF Envelope view. That is because an I only or Q only waveform determines the I only or Q only signal envelope. Thus, the RF Envelope view can be used to measure an I only or Q only waveform directly.

 noise
 band power marker 76

F
factory preset, description 11
finding hidden signals 158
FM demodulation
 time-domain demodulation,
 manually calculating 182
frequency accuracy, increasing 13
frequency readout resolution increased 54
front panel
 entering data 10

gate delay
 setting the gate delay, time gating 175
gate length
 setting the gate length, time gating 175
gated FFT (PSA), concepts 168
gated LO (PSA), concepts 167
gated video (ESA), concepts 167
GPIB cable 17

H
harmonic distortion
 measuring low-level signals 23

I
identifying distortion products 62
initial setting for time gating 178
input attenuation, reducing 42
intermodulation distortion, third order 65
interval power marker function 37
iq waveform measurement 183
Index

K
keypad, using 10
knob, using 10

L
limiters
RF and transient 17
load, 50 ohm 16
low-level signals
harmonics, measuring 23
input attenuation, reducing 42
resolution bandwidth, reducing 45
sweep time, reducing 48
trace averaging 50

M
marker
frequency and amplitude, reading 12
moving
to reference level 12
with knob or arrow key 12
marker annotation
location 12
marker counter example
marker frequency resolution 54

noise marker 72
overview 70
signal to noise 70
time gating 91
ESA-E time gate 102
PSA gated FFT 106
PSA gated sweep 98
moving signals 59
noise power measurement near noise 86
numeric keypad, using 10

N
noise marker 81
noise measurements
band power marker, using 76
channel power, using 79
noise marker, using 72
overview 70
signal to noise 70
sweep time, reducing 48
noise power measurement near noise 86

O
occupied bandwidth
99.0% bandwidth 187
measurement method 187
purpose 187
total absolute power 187
overview 112
Occupied Bandwidth measurement
distortion 62
low-level signal 42
noise 70
resolving signals 158
time gating 164

P
positioning the gate, time gating 174
power amplifiers 17
power diff
trace math function 86
power splitters 18
preamplifiers 17
preset
factory 11
types 11
user, creating 11
probes
AC and DC 16

R
RBW selections 47
reference level, setting 12
resolution bandwidth
adjusting 45
resolving signals 158
resolving signals
small signals hidden by large signals 158
resolving two signals
equal amplitude 26, 158
resolving, equal amplitude 158
RF limiters 17
RPC, using 10
rules for time gating 177

S
signal parameters for a time-gated
measurement 172
signal tracking
example 59
marker tracking 35
using to resolve signals 35
signals
