Keysight Technologies
Quickly Validate Designs for DOCSIS 3.1 Compliance

Application Brief

Accelerate research and development and design verification test of DOCSIS 3.1 designs with a cost-effective, standards-based measurement solution, that provides high speed, wide bandwidth, deep memory and flexibility.
Abstract

The latest version, DOCSIS 3.1, of the Data Over Cable Service Interface Specification (DOCSIS) standard, has now been officially released. Designing DOCSIS 3.1-based transmitters, receivers and components, and verifying their performance against the new standard requires stringent testing - a process made more complex by the standard's adoption of new technologies and the need for backward compatibility with previous DOCSIS versions.

This document describes the Keysight Technologies, Inc. portfolio of DOCSIS 3.1 test solutions − hardware and software to generate and analyze signals up to 192 MHz bandwidth, as shown in Figure 1. These solutions can be used to test transmitters, receivers and components against the new requirements set forth in the DOCSIS 3.1 specification.

Introduction

Over the years, the DOCSIS standard evolved to meet the needs of cable operators and their subscribers. Emerging applications like HDTV video streaming around the home and in-room gaming, is driving demand for multi-gigabit data rates. The need for increased bandwidth led to the latest standard revision – DOCSIS 3.1.

DOCSIS 3.1 provides a way for cable operators to increase capacity and speed, with up to 50 percent more data throughput over the same spectrum than DOCSIS 3.0, and the ability to deliver 2.5 Gbps in the upstream and 10 Gbps in the downstream on an existing hybrid fiber-coaxial (HFC) network. Its efficient spectrum use enables a significant decrease in the cost per bit for data delivery. This provides cable operators a competitive advantage over satellite and wireless providers in the hotly contested battle for today’s bandwidth-hungry broadband data subscribers.
DOCSIS 3.1 achieves its increased speed and capacity through its use of orthogonal frequency-division multiplexing (OFDM) and low-density parity-check (LDPC) forward error correction (FEC) technology. The standard mandates the use of up to 4096 QAM modulation with a 24 to 192 MHz channel bandwidth in the downstream, and up to 4096 QAM modulation with up to a 96 MHz bandwidth in the upstream. It also supports pure IP payload data and can co-exist with legacy channels on the existing HFC infrastructure.

While these technologies enable needed capacity and speed improvements, they also pose a number of new challenges in design and test; namely the generation and analysis of wider bandwidth signals for DOCSIS 3.1’s 192 MHz channel. Many generators simply do not have a high enough sampling rate to support the typical minimum 2x oversampling ratio needed for signal generation. Without this support, images can occur in the signal due to aliasing. Additionally, finding a test solution that can handle the complexity of OFDM and LDPC FEC, and supports legacy DOCSIS technologies, while also being cost-effective, fast, and flexible enough to accommodate future standard revisions can also be problematic.

Solution overview

Keysight’s solution for DOCSIS 3.1 test, shown in Figure 2, features the M9703A AXIe high-speed digitizer, its PCIe® version, the U5303A, and the M8190A arbitrary waveform generator (AWG). Keysight’s 89600 VSA software (with OFDM demodulation option BHF) and SystemVue electronic system level (ESL) design software, generates fully coded DOCSIS 3.1 waveform files that can be generated using the M8190A AWG.

Signal Generation (192 MHz bandwidth)
- DOCSIS 3.1 upstream and downstream statistically correct waveform files
- N7623B Signal Studio for Digital Video to generate fully-coded DOCSIS 3.1 waveforms
- Waveform Creator software tool to generate and modify statistically correct DOCSIS 3.1 waveform files
- SystemVue software tool to generate and modify fully coded DOCSIS 3.1 waveform files
- Selection of arbitrary waveform generators (AWGs) to generate 192-MHz bandwidth DOCSIS 3.1 signals

Signal Analysis (192 MHz bandwidth)
- 89600 VSA software supporting multiple hardware platforms offering greater than 192-MHz bandwidth demodulation capability
- 896018-BHM: DOCSIS 3.1 Downstream modulation analysis (MER & BER)
- Custom OFDM modulation analysis with option BHF (DS/US MER)
- Digitizers configured as 4-and 1-channel are able to capture DOCSIS 3.1 192-MHz bandwidth signals
- Spectrum analyzers able to support DOCSIS spectral measurements
- SystemVue’s DOCSIS library can be used to demodulate and decode DOCSIS 3.1 downlink signals

The M9703A is an 8-channel, 12-bit wideband digital receiver/digitizer. Its channel interleaving capability enables a 4-channel configuration to capture DC to 1.4 GHz signals for DOCSIS 3.1 waveform acquisition at up to 3.2 GS/s. This configuration provides exceptional measurement accuracy.

The U5303A, option D31, is a single slot, 12-bit, PCIe 2-channel digitizer. Its channel interleaving capability enables a 1-channel configuration to capture DC to 1.4 GHz signals for DOCSIS 3.1 waveform acquisition at up to 3.2 GS/s. This configuration enables the U5303A-D31 to deliver the performance necessary to meet the new DOCSIS 3.1 test requirements at a low cost.

The M8190A, a 12 GS/s, 2-channel AWG, features 2-GS memory per channel, 5-GHz analog bandwidth and up to 90 dBC SFDR.

Such deep memory, wide bandwidth and excellent SFDR, coupled with its inherent flexibility, enable the M8190A to...
Solution details

Transmitter Test

Testing a DOCSIS 3.1 transmitter requires both a Keysight high-speed digitizer and 89600 VSA software with option BHF. Together, the two can demod and analyze statistically correct wideband signals (up to 192 MHz) with a -50 dB MER or better.

A test setup for DOCSIS 3.1 transmitter testing is shown in Figure 3. The M9703A or U5303A-D31 digitizer effectively captures the wide bandwidth signals, while the 89600 software demodulates and analyzes them. 89601B-BHM, DOCSIS 3.1 Downstream analysis option provides the deeper insight of demodulated results along with MER and BER reports. With the custom OFDM demodulation capability, engineers can even define their own custom OFDM signal parameters. For spectral tests, Keysight’s signal analyzer is required.

A portable test solution that complements the use of the MXA is shown in Figure 4.

Receiver Test

A setup for performing a DOCSIS 3.1 receiver test is shown in Figure 5. Testing the receiver requires both the wideband M8190A AWG and SystemVue software. DOCSIS 3.1 waveforms are created using Signal Studio, Waveform Creator or SystemVue, depending on the level of complexity required, and downloaded to the M8190A, which generates the signals required for test. Together, the M8190A and Waveform Creator or SystemVue software can be used to realistically stress DOCSIS 3.1 signals during receiver test and simulate signals over the whole HFC bandwidth, up to 1.2 GHz, for transmission network test.

Component Test

During component test, the M8190A AWG and M9703A/U5303A-D31 digitizers are both employed, along with the 89600 VSA with Option BHF and Waveform Creator or SystemVue software to offer a fully coded stimulus and response test system.

In the R&D environment, SystemVue’s simulation library can create multi-format signals and demodulate received waveforms to recover DOCSIS 3.1 coded bit sequences, supporting BER and other system-level investigations.
