Chapter 1: Introduction

Many designers would like to take advantage of the powerful simulation capabilities of Advanced Design System (ADS) from Agilent Technologies. In order to use ADS effectively, designers must have access to a set of required models. Agilent Technologies is addressing this need by providing the translated ADS model files for distribution in the form of ADS design kits. With the information provided in this document, the models used in these ADS design kits can be verified against other simulator models such as Hspice and Spectre.

Advanced Design System

Advanced Design System has been developed specifically to simulate the entire communications signal path. This unique solution integrates the widest variety of proven RF, DSP, and electromagnetic design tools into a single, flexible environment. Building on years of expertise developing new technologies for our EDA tools, such as Series IV and MDS, Advanced Design System provides a broad range of high-performance capability. This makes it easy to explore design ideas, then model the electrical and physical design of the best candidates.

ADS Design Kit Model Verification Tool

Verification of the translated design kit models is one of the most important steps in the overall design kit creation process. This step is typically the most technically challenging and time consuming. The ADS Design Kit Model Verification process utilizes a library verification tool that helps to simplify many of the steps required to verify device models for use with a foundry's device and process parameter sets. This Perl script driven tool is used to verify that results from the ADS simulator match the output from the native simulator for design kit models that were translated from other formats such as Hspice or Spectre.

The model verification tool verifies that the outputs from the ADS simulator match the results from the foundry benchmark data to within a specified margin of error. The foundry benchmark data is typically the output from SPICE simulations of the foundry's test circuits. For more information on simulators supported by the Design Kit Model Verification tool, refer to “Supported Simulators” on page 2-1.
Introduction

Intended Audience

The audience intended for this manual consists of people involved in ADS design kit creation and model verification. The audience includes design kit developers and CAD administrators. Because the ADS Design Kit Model Verification tool is a script driven tool, the audience using this manual is expected to know some Practical Extraction Report Language (Perl) scripting and object oriented programming in order to perform advanced operations.

For simple circuits, you may be able to perform a verification with minimal Perl scripting knowledge. This document has been written to include examples for those who might not have the skills, but still want to verify simple circuits. The document provides predefined scripts that you can copy and modify for basic operation.

If you are a novice Perl user, review the section on “Using Perl” on page 2-1 to help you get started.

The Design Kit Model Verification Tool Process

The basic steps for using the ADS Design Kit Model Verification tool are as follows:

1. Install the default template and parameter modules.
2. Build a script header to use in your own scripts.
3. Create any custom template & parameter scripts and then add them to the default modules.
4. Create a test script and run it to simulate your test circuits.
5. If you receive errors, review the error logs, modify your scripts to correct the errors, and re-run the simulation.
6. If no errors occur, set up an ADS Data Display template to view your results.
7. Compare your simulation results between the different simulators.

Chapter 3, Building a Basic Script describes the details for performing the operations listed above. Figure 1-1 on the following page shows a simple process flowchart of the process described above.
Create Custom Templates / Parameters and Add to Default

Introduction

What’s in this Manual

This guide contains the information needed to verify an ADS design kit model against another simulator design kit model. Most of the details are applicable for all work involving design kit model verification but some optional steps may be skipped for simpler kits or smaller installations.

- **Chapter 2, Setting up the Design Kit Model Verification Tool** describes the information needed to setup the design kit model verification tools such as setting up environment variables.

- **Chapter 3, Building a Basic Script** provides several examples that describe the steps necessary for using the design kit model verification tool. These steps are briefly described in “The Design Kit Model Verification Tool Process” on page 1-2.

- **Chapter 4, Building an Advanced Script** provides an example of building a more complex design kit test circuit script. The end of the chapter also provides several tables that describe the functions available in the design kit model verification tool. These tables give a description for each function as well as usage syntax.

- **Chapter 5, Comparing Simulation Results** describes how to setup templates for viewing your simulation results within an ADS Data Display and how to do script based comparisons.

- **Chapter 6, Documenting Your Simulation Results** describes the fundamentals of using the ADS Electronic Notebook.

Minimum ADS Installation Requirements

**ADS 2001** or later is the minimum requirement for using the ADS Design Kit Model Verification Tool described in this manual.
Chapter 2: Setting up the Design Kit Model Verification Tool

This chapter describes the operations necessary for setting up the ADS Design Kit Model Verification Tool.

Supported Simulators

There are several simulators currently supported by the ADS Design Kit Model Verification Tool. All simulators currently supported by the verification tool are listed in Table 2-1.

Table 2-1. Design Kit Model Verification Tool Supported Simulators

<table>
<thead>
<tr>
<th>Vendor</th>
<th>Simulator</th>
<th>Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agilent Technologies</td>
<td>hpeesofsim</td>
<td>hpeesofsim 2001 and later</td>
</tr>
<tr>
<td>Avant! Corporation</td>
<td>Hspice</td>
<td>2000.2 and later</td>
</tr>
<tr>
<td>Cadence Design Systems Inc.</td>
<td>Spectre</td>
<td>4.4.5/4.4.6/5.0.0</td>
</tr>
</tbody>
</table>

Additional simulators to those listed in Table 2-1 may be supported in future revisions of the ADS Design Kit Model Verification Tool. For more information on supported simulators, consult your Agilent Technologies sales representative.

Using Perl

Practical Extraction Report Language (Perl) is a scripting language widely used for system administration and programming on the World Wide Web. The Design Kit Model Verification tool makes extensive use of Perl scripts in order to provide the flexibility to write and customize your own perl scripts. The Design Kit Model Verification tool is currently script driven only and has no user interface (UI). The thought behind making this tool script driven only was that even if a UI had been implemented, most users would quickly revert to using scripts to use the tool due to its ability to be called by other perl scripts.

Perl scripts are made up of a list of statements (terminated by semicolons) and declarations. The first line of a perl script uses the #! symbols followed by the full path name of the directory where the version of Perl resides (see “Using Perl on UNIX” on page 2-3). When Perl detects the comment character (#) within the
program, it ignores the rest of the line. Many of the examples in this document use several comment characters to denote information about the lines of code following the comments. The comment character is a good tool for helping you to document your own perl scripts within the code.

**Note** On unix, the first 16 bits (2 bytes) of a file determine its file type. The `#!` placed as the first characters on the first line are the first 16 bits that indicate this file type is a shell script file where the script interpreter is given next. So, first having a blank line and then a line with `#!` does not work - in this case, `#!` is simply a comment.

On all systems, you run your Perl script by providing the script name as a parameter to the Perl interpreter. For example, if you had created a script called, `myPerlScript.pl`, you would enter the following command to execute the script:

```
perl myPerlScript.pl
```

Perl statements can be simple or compound statements, consisting of a variety of operators, modifiers, expressions, and functions. The ADS design kit model verification tool provides a predefined selection of functions that help you build your script. As you become more proficient in building your scripts, you will find that modification of existing scripts is a simple way to add to your design kit model verification tool set.

**Note** that within your perl scripts, it is required to use vertical quoted strings (`'<string>'` or `"<string>"`) wherever the chosen value happens to be a perl command, otherwise your script will not run correctly. Within the perl scripts, it is highly recommended that you quote all strings to reduce the possibility of generating errors.

**Note** In perl, single quotes (`'<string>'`) represent text as is, with no variable substitution. Double quotes (`"<string>"`) perform variable substitution. For example, `"$myVar"` will be substituted by its value if it is in double quotes, while `'$myVar'` will just be equal to `$myVar` if it is in single quotes.

Perl originated in the UNIX community and therefore has a strong UNIX slant; however, usage within the Windows community is growing rapidly. ActivePerl is a port of core Perl to Windows.

For detailed information on the Perl scripting language, refer to [http://www.perl.com](http://www.perl.com) on the O'Reilly & Associates, Inc. network.

---

2-2 Using Perl
The Perl scripting language is interpreted by a program called, perl (note the small 'p'). Advanced Design System contains a perl executable (perl) that is located under:

   $HPEESOF_DIR/tools/bin   (on unix)

and

   $HPEESOF_DIR/tools/perl/bin   (on PC)

Using Perl on UNIX

Typically, the Perl program is run by either making it directly executable, or by passing the name of the source file as an argument in the command line. When possible, it is beneficial for both /usr/bin/perl and /usr/local/bin/perl to be symbolic links to the actual binary file. If this is not possible, system administrators are strongly encouraged to add symbolic links to perl and its accompanying utilities into a directory typically found along the user's PATH, or some other convenient location.

Note: In the design kit model verification tool perl scripts, the ADS version of perl is used.

Using Perl on Windows

When using the ActiveState installer for Perl, a WinNT installation modifies the Registry to associate the .pl extension with the perl interpreter. If you install Perl by other means (including building from the sources), you may have to modify the Registry yourself. Note that this means that you can no longer tell the difference between an executable Perl program and a Perl library file. If you do not want to modify the registry, the perl <sourcefile> command from a shell window should run as on unix if the PATH variable is correctly defined.

If the invocation of the different simulators does not succeed as planned, try to use the cygnus bash shell on the PC (located in $HPEESOF_DIR/tools/bin) for running your perl scripts (see “Configuring the Environment” on page 2-4).
Setting up the Design Kit Model Verification Tool

**Note**  When running a perl command you may get the error, can't open perl script 
"/ <path2file>": No such file or directory. This is because your current directory is not 
on the same drive as the perl file you want to access. To solve this you must run the 
command as perl <drive_letter>/<path2file>.

---

### Configuring the Environment

Upon installation, the verification tool attempts to find all files in the directory tree 
pointed to by an environment variable called DKitVerification. All executable 
files are located in the $DKitVerification/bin directory. If you are using the 
standard installation, you can add DKitVrun before any verification tool command 
which will set-up the verification tool specific environment correctly so the command 
will run. For example:

```bash
dKitVrun dKitTemplateCreate.pl
```

The dKitVrun command is located in $HPEESOF_DIR/bin.

To avoid using dKitVrun, you can setup the environment variables yourself. When 
the verification tool is installed, the dkitverification install directory is 
$HPEESOF_DIR/design_kit/verification.

**Note**  $HPEESOF_DIR is the location of the ADS installation (see “Developing the 
Script Header” on page 3-2).

To ease the use of the verification tool, add the declaration of this variable to the 
initialization scripts.

**For UNIX:**

Append the following to your,

~/.profile if you are using the Korn shell:

```bash
export DKitVerification=<dkitverification install directory>
export PATH=$PATH:$DKitVerification/bin
```

Or

~/.cshrc if you are using the C shell:

```bash
```
setenv DKITVERIFICATION <dkitverification install directory>
setenv PATH $PATH:$DKITVERIFICATION/bin

After adding the environment variables to the initialization file, either re-logon or source your initialization file using one of the following commands:

. ~/.profile for the Korn shell

Or

source ~/.cshrc for the C-shell

For the PC:
Set the system wide Environment variable

  DKITVERIFICATION <dkitverification install directory>

and add

  DKITVERIFICATION\ bin

to the PATH using the Start > Settings > Control Panel, System tool.

On some PC operating systems, it might be necessary to directly run the perl scripts from within a Cygnus shell. To configure the shell:

1. Start a cygnus shell ($HPEESOF_DIR/tools/bin/bash.exe).
2. Issue the following commands to mount the necessary bin directories:

    mount $HPEESOF_DIR/tools/bin /bin
    mount $HPEESOF_DIR/tools/bin /usr/bin

Modifying the Source Code

If you have a need to modify the source code, you must copy the entire verification tree to another directory (e.g. $HPEESOF_DIR/custom/verification), and set the DKITVERIFICATION environment variable accordingly. If you copy the entire verification tree to another directory, you will not be able to use the dKitVrun utility as described in “Configuring the Environment” on page 2-4 unless you edit it and change the paths accordingly.
Prior to Running a Script

Before attempting to develop a perl script and run the verification tool as described in Chapter 3, Building a Basic Script or Chapter 4, Building an Advanced Script, it is important to ensure that your environment has been configured properly and all of the default parameter and template modules have been created.

To quickly setup a new work directory for running the design kit model verification tool, create a new directory and from within that directory, issue the following command.

   dKitSetupWork.pl

Also, verify that your PATH has been modified so that the hpeesofsim, spectre and hspice simulators can be found and the correct environment variables have been set for them to work. For more information on configuring your environment for these simulators, consult the appropriate simulator installation documentation.
Chapter 3: Building a Basic Script

This chapter describes how to setup and build a simple script to create a netlist and run a simulation using the design kit model verification tools. A tutorial example is provided that will help you understand the fundamental requirements for verifying a simple circuit.

The example commands given should run as is on supported unix systems or from within a cygnus shell on a PC, provided that the environment (see “Configuring the Environment” on page 2-4) and script headers (see “Developing the Script Header” on page 3-2) are correctly configured.

**Note**  
Within the perl scripts, it is required to use vertical quoted strings wherever the chosen value happens to be a perl command, otherwise your script will not run correctly. Within the perl scripts, it is highly recommended that you quote all strings to reduce the possibility of generating errors. Open quotes (‘<myString>’) are not allowed for quoting strings in Perl and vertical quotes (’<myString>’) should be used instead. Perl uses the open quote character for other applications.

The three main requirements to create and run a design kit model verification script are:

- “Understanding Templates” on page 3-4
- “Understanding Parameters” on page 3-8
- “Creating a Test Circuit” on page 3-10

Understanding Items and Handles

A netlist is a succession of lines describing the test circuit. Each element (instance, analysis, parameter, etc.) of a circuit is referred to as an item in the design kit model verification tool. Generally speaking, each item corresponds to one line in a netlist file. In the design kit model verification tool, the context of an item has been generalized. For instance, dKit circuits, dKit parameters and dKit templates are also items. Therefore, the complete test circuit is also considered an item.

To create a netlist with the design kit model verification tool, a perl script is needed. Within the perl script, items are created by means of the call to a `new()` function. The return value of that function is called a handle. The implementation of the functions
Building a Basic Script

used in the design kit model verification tool reside in the design kit modules. Hence you get the following syntax:

\$<handle> = <design_kit_module>->new(<arguments>);

For example, in perl syntax:

\$myResistor = dKitInstance->new('R', 'R1');

In the example above, \$myResistor is a handle to the item R1, (which is currently a non-connected resistor with an undefined resistor value).

Another example, in perl syntax:

\$myCircuit = dKitCircuit->new("test1");

In this example, \$myCircuit is a handle to an empty circuit, called test1.

Subsequent operations on this handle would then complete the definition of the item. For example:

\$myCircuit->addInstance(\$myResistor);

would define \$myResistor (R1) to actually belong to \$myCircuit (test1).

Yet another example:

\$myResistor->parameterValue('resistance', 10);

defines \$myResistor to be a 10 Ohm resistor.

For detailed information on using items and handles, refer to Chapter 4, Building an Advanced Script.

Developing the Script Header

The first step in creating your own perl script is to build a script header that will ensure that the correct modules are found by the script.

To begin developing your perl script header:

1. Open any ASCII text editor and copy the lines of code shown in Table 3-1 to the beginning of your new file.
Table 3-1. Perl Script Header

```perl
#!<myPath2perl>/perl
BEGIN {
  if ($ENV{DKITVERIFICATION} eq "")
  {
    if ($ENV{HPEESOF_DIR} eq "")
    {
      print "Please set environment variable DKITVERIFICATION to point to the design kit model verification installation directory\n\n";
      exit 1;
    } else
    {
      $ENV{DKITVERIFICATION} = "$ENV{HPEESOF_DIR}/design_kit/verification";
    }
  }
  $myLibPath = "$ENV{DKITVERIFICATION}/perl/lib";
  if ( ! -d $myLibPath)
  {
    if ($ENV{DKITVERIFICATION} eq "$ENV{HPEESOF_DIR}/design_kit/verification")
    {
      if ( ! -d "$ENV{HPEESOF_DIR}/design_kit/verification")
      {
        print "ERROR: Unable to find verification module directory\n        \$HPEESOF_DIR/design_kit/verification\n";
        print "Please set environment variable DKITVERIFICATION to point\n        to the design kit model verification installation directory\n        \n";
      } else
      {
        print "ERROR: Unable to find verification module directory\n        at default location \$HPEESOF_DIR/design_kit/verification/perl/lib\n";
        print "Please set environment variable DKITVERIFICATION to point to the installation directory\n        \n";
      }
    } else
    {
      print "ERROR: Unable to find verification module directory\n        \$DKITVERIFICATION/perl/lib\n";
    }
  } else
  {
    print "\nERROR : Unable to find verification module directory\n        \$DKITVERIFICATION/perl/lib\n";
  }
  exit 1;
}
# To find the standard supplied libraries in the local path
use Cwd;
$curDir = cwd;
}
use lib "$myLibPath";
use lib "$curDir";
```
Building a Basic Script

2. Replace the first line in the file header in Table 3-1 with the path to the perl interpreter. The default path is `/usr/bin/perl`; however, your path may be different.

3. Save this new file as header.pl so it can be copied and re-used in later scripts.

A sample script is included in the design kit model verification tool, at the location $HPEESOF_DIR/design_kit/verification/perl/header.pl

Understanding Templates

In a previous section, “Understanding Items and Handles” on page 3-1, it was shown that a test circuit in the design kit model verification tool consists of handles to items. When the netlist for the simulator needs to be created, the design kit model verification tool needs to know how to do this. This is where templates are used. A template, as such, can be seen as the set of rules for how to translate the handle in the perl test circuit script to a netlist segment for each of the different simulators. This means that one template is required for each type of component/analysis/... used in the test circuit. Different instances of the same component/analysis will use the same template.

Templates are made available to the design kit model verification tool by means of a perl database file dKitTemplateDB.pl. So if you do not see the file dKitTemplateDB.pl within your working directory, you have not installed any templates.

To view which templates are currently available:

- Run the perl script dKitTemplateList.pl. This script will list all currently defined templates, with the enumeration of their nodes, parameters and simulator translation rules.
- Alternatively, you can just look at the dKitTemplatesDB.pl file if you are a perl expert.

Installing the Default Templates

For standard components (R, L, C, M, Q, etc.), circuit parameters and standard analyses (DC, AC, Noise and S-parameter), the design kit model verification tool distribution includes a perl script that contains the standard template definitions. To install the standard templates, move to your working directory and issue the command:

```bash
dKitTemplateCreate.pl
```

---

3-4 Understanding Templates
This command creates the file dKitTemplateDB.pl with a set of standard templates for your design in your working directory. Once created, the dKitTemplateDB.pl file makes these templates available to be called by your test circuit perl script.

**Note** This command deletes previously installed custom templates, so you will need to rerun your custom template scripts to reinstall the custom templates.

## Creating Custom Templates

This section provides a step-by-step example for creating a simple custom component template. A custom component is any component that is not part of the standard component set provided with Advanced Design System. More in particular, a custom component is one that is using a model defined within the model library file. For custom components, the templates need to be created separately.

To define a custom component template:

1. Open a copy of the header.pl script that was created in “Developing the Script Header” on page 3-2.

2. Add the following line to the end of the header.pl script to initialize your custom template.
   
   ```perl
   use dKitTemplate;
   ```

3. Start defining your custom component template by creating a handle for the template structure. For example, adding the following command will create a new design kit template with a handle of my_2p.

   ```perl
   $my_2p = dKitTemplate->new('my_2p');
   ```

   If the handle you created for your template already exists, a template already defined error will be reported when you try to re-run your script. To avoid template handle duplication errors, run the default design kit template creation script again before re-running your script. For more information on the default design kit template creation script, refer to “Installing the Default Templates” on page 3-4.

   Alternatively, you can query to see if a template already exist before defining a new one, by adding the following lines to your script instead of just defining a handle.

   ```perl
   if ( ! ($my_2p = dKitTemplate->getTemplate('my_2p')) )
   ```
Building a Basic Script

```c
{
    $my_2p = dKitTemplate->new('my_2p')
} else
{
    print "redefining my_2p\n"
}
```

Adding the code above will result in the my_2p handle being redefined if another instance of my_2p already exists. For more information on handles, refer to “Understanding Items and Handles” on page 3-1.

4. Once you have designated a handle for your template, you can start defining your template dialects. The following example shows a simple template using the handle created earlier in step 3.

```c
$my_2p->netlistInstanceTemplate('ads', '<model>:#instanceName %n1 %n2 [[count=<count>]]');
$my_2p->netlistInstanceTemplate('spectre', '#instanceName %n1 %n2 <model> [[count=<count>]]');
$my_2p->netlistInstanceTemplate('hspice', '#instanceName %n1 %n2 <model> [[count=<count>]]');
```

The example above shows the itemType my_2p defined to be a component with two nodes n1, and n2 (see %n1, %n2), and 2 parameters, model and count (see <model>, <count>). The [[ ... ]] syntax means that the parameter count is optional. The #instanceName is an internal function which will return the name of the item.

This template could for instance be used to define a component with 2 nodes whose model name is <model> and has a parameter called <count>, defined in the model library files of the different simulators.

---

**Note**  The number of nodes and the name of the parameters used by the template is the number of nodes defined and the names of the parameters in the model library file. The number of nodes and the names of the parameters defined in the design kit customization files are ignored by the design kit model verification tool. The design kit customization files are the .ael files, which define the components (items) to be used on the schematic (item definition).

For more information on the template module, and a more rigorous explanation of the syntax, refer to “Template Module” on page 4-3.

---

3-6 Understanding Templates
5. Once you have completed all of your template definitions, add the following line as the last line of your test script:

```
dKitTemplate->createTemplateDatabaseFile;
```

This command will add your custom template definition to the default templates.

6. Save your new script as `myTemplates.pl` or some other appropriate name. An example of what your new script might look like is shown in Table 3-2.

7. Run the new perl script to add your custom templates to the default templates in the file `dKitTemplateDB.pl`. You can now use your custom templates when creating your design kit test circuit.

```
#!/usr/bin/perl

# ADD SCRIPT HEADER from Table 3-1.

### Initialize the new template.
use dKitTemplate;

### Query to check for template duplication errors.
if ( ! ($my_2p = dKitTemplate->getTemplate('my_2p')) )
{
    $my_2p = dKitTemplate->new('my_2p')
} else
{
    print "redefining my_2p\n";
}

### Set the template dialects.
$my_2p->netlistInstanceTemplate('ads', '#instanceName %n1 %n2 [[count=<count>]]');
$my_2p->netlistInstanceTemplate('spectre', '#instanceName %n1 %n2 <model> [[count=<count>]]');
$my_2p->netlistInstanceTemplate('hspice', '#instanceName %n1 %n2 <model> [[count=<count>]]');

### Add the template definition to the default template.
dKitTemplate->createTemplateDatabaseFile;

### end of script
```

Table 3-2. Perl Script with a call to dKitTemplate
Understanding Parameters

The parameters of devices in different simulators use different names. Ideally, you want the parameters of devices in your results file to have the same name. The design kit model verification tool includes a parameter module to map the different parameter names for the same parameter to one unique name.

Parameters are made available to the design kit model verification tool by means of a perl database file dKitParameterDB.pl. So if you do not see the file dKitTemplateDB.pl within your working directory, you have not installed any parameters.

To view which parameters are currently available, run the perl script dKitParameterList.pl. This script will list all currently defined parameters. Alternatively, you can just look at the dKitParameterDB.pl file if you are a perl expert.

Installing the Default Parameters

Again, there are default parameters defined. To install them into your working directory, enter the command:

    dKitParameterCreate.pl

This command creates the file dKitParameterDB.pl with a set of standard templates for your design in your working directory. Once created, the dKitParameterDB.pl file makes these parameters available to be called by your test circuit perl script.

Note This command deletes previously installed custom parameters, so you will need to rerun your custom parameter scripts to reinstall the custom parameters.

Creating Custom Parameters

Once your default parameters are installed, you can start creating your new design kit parameters in a perl file.

To create your new parameter file:

1. Open a copy of the header.pl script that was created in “Developing the Script Header” on page 3-2.
2. Add the following line to the end of the header.pl script to initialize your custom template.

```perl
use dKitParameter;
```

3. To define a custom parameter, you must create an instance and define the different instance parameters. For example:

```perl
$IDC = dKitParameter->new('Idc'); # The dKit Parameter Name
$IDC->description("dc current"); # Its description
$IDC->dialectReference('hspice', 'dc'); # Its name in hspice
$IDC->dialectReference('ads', 'Idc'); # Its name in ads
$IDC->dialectReference('spectre', 'dc'); # Its name in spectre
$IDC->resultName("dc"); # The name used for the results
```

The dKit Parameter Name is the name to use for device parameters within the test circuit perl script. The netlister will translate it to the simulator parameter name. For more information, refer to “Parameter Module” on page 4-9.

4. As with the templates, it is beneficial to add new parameter definitions to the default parameter definitions using the command:

```perl
dKitParameter->createParameterDatabaseFile;
```

Your new script should now appear similar to Table 3-3. Run the script after entering this command to update the parameter information.

```
#!/usr/bin/perl

use dKitParameter;

### add the perl commands to create the parameters here.
$IDC = dKitParameter->new('Idc'); # the dKit Parameter Name
$IDC->description("dc current"); # its description
$IDC->dialectReference('hspice', 'dc'); # its name in hspice
$IDC->dialectReference('ads', 'Idc'); # its name in ads
$IDC->dialectReference('spectre', 'dc'); # its name in spectre
$IDC->resultName("dc"); # the name used for the results

dKitParameter->createParameterDatabaseFile;

### end of script
```

Table 3-3. Perl Script for Custom Parameters
Building a Basic Script

Creating a Test Circuit

Once your templates and parameters are defined and installed, you can start creating your design kit test circuit in a new perl file. This section provides examples for creating a simple test circuit.

The following example illustrates many of the issues typically encountered when building a test circuit. Each of the sections shown below discusses an aspect of creating the test circuit perl script. While all portions of the creation process may not be used in your script, each section should be addressed in the order given.

1. “Setting up a Test Circuit” on page 3-11
2. “Adding Circuit Options” on page 3-12
3. “Adding Model Library Files” on page 3-13
4. “Creating Instances” on page 3-14
5. “Connecting Instances” on page 3-15
6. “Creating Analyses” on page 3-15
7. “Transient Analysis timeStepMethod Parameter” on page 3-18
8. “Defining the Simulators” on page 3-18
9. “Running the Test Circuit Script” on page 3-22
Setting up a Test Circuit

To create a new test circuit perl script:

1. Open a copy of the header.pl script that was created in “Developing the Script Header” on page 3-2.

2. Add the following line to the end of the header.pl script. This line is used to initialize your new test circuit.

   use dKitCircuit;

3. Create the circuit handle for the structure by adding the following function:

   $Circuit = dKitCircuit->new('<circuitName>');

   Where <circuitName> determines where to store the intermediate and final results. If the name contains slashes (/), subdirectories are created for storing the intermediate results and the final result (<circuitName>.cti or <circuitName>_<simulator>.cti) in CITI file format.

   The dataset used to view the results in the ADS Data Display will be placed in the current directory. The ADS Data Display file name is in the form <circuitName>.ds or <circuitName>_<simulator>.ds where the slashes (/) are replaced by underscores (_). For example, if <circuitName> equals myTests/test1 then all intermediate files are stored in the directory myTests, and will start with the prefix test1. The resulting dataset will be called myTests_test1.ds or myTests_test1_<simulator>.ds. The _<simulator> is added to the final results name if you request a simulation for only one simulator.

   For more information on datasets (.ds) and CITI file (.cti) format, refer to Chapter 7 of the ADS “Circuit Simulation” documentation.

4. Save a copy of your new file as myCircuit.pl.
Building a Basic Script

Adding Items

The content of your circuit is defined by adding items as needed to your script using the `new()` function.

To create a new item, use the function in the general form:

```
new('<templateName>', '<itemName>');
```

Each `<itemName>` should be a unique identifier. For more information on items, refer to “Understanding Items and Handles” on page 3-1.

**Note**  Item names are case sensitive. Therefore, `Optional1` is not equal to `optional1`. Also, because HSpice translates everything to lower case in the results file, comparisons will be easier when only lower case itemNames are used.

Adding Circuit Options

The Options component makes it possible to set general simulation options related to convergence tolerances, warnings, global noise temperature and so on. To set an Option other than the standard circuit Options:

1. Create the Option handle.
2. Define the simulator parameter values.
3. Add the simulator option to the circuit.

The following example shows a typical simulator options setup:

```
$OPTION1 = dKitInstance->new('SIMULATOROPTION', "option1");
$OPTION1->parameterValue('adsOptions', "ResourceUsage=yes");
$OPTION1->parameterValue('spectreOptions', "save=lvlpud digits=10");
$OPTION1->parameterValue('hspiceOptions', "nopage acct=0 dccap=1 numdgt=10");
$Circuit->addSimulatorOption($OPTION1);
```

Temperature is handled somewhat differently than other options. For example, to set the circuit temperature at 20 degrees Celsius, you need the following:

```
$TEMP = dKitInstance->new('TEMPERATURE', 'T1');
$TEMP->parameterValue('temperature', 20);
$Circuit->addSimulatorOption($TEMP)
```
If you plan to do a temperature sweep, it is better to not add a default temperature option, as this might cause problems when doing Hspice simulations.

You can add multiple option instances; however, ensure that you give each option a unique name. For example, option1, option2, option3, etc.

**Adding Model Library Files**

The modelLibrary item enables you to build a list of model files that you want to include in your test circuit.

To add a modelLibrary item to your circuit:

1. Create a modelLibrary handle.
2. Add the path to the variables and equations data.
3. Set the path and Section parameters if needed (see “Adding a Model Library Section Designator” on page 3-13).
4. Add the modelLibrary to the circuit.

For each additional library or library Section, you must create and add a new model library handle. The following example shows a typical modelLibrary item setup.

```plaintext
$MODLIB1 = dKitInstance->new('MODELLIBRARY', "vars");
$MODLIB1->parameterValue('adsModelLibrary', "../models/ads/vars.net");
$MODLIB1->parameterValue('spectreModelLibrary',"../models/spectre/vars.scs");
$MODLIB1->parameterValue('hspiceModelLibrary',"../models/hspice/vars.hsp");
$Circuit->addModelLibrary($MODLIB1);
```

**Note**   When using relative paths, please note that the simulator actually changes the working directory to the `<circuitName>` directory before it starts the simulator. For more information, refer to “Setting up a Test Circuit” on page 3-11.

**Adding a Model Library Section Designator**

Each model file can have a Section designator. This enables you to include only a portion of a model file for corner analysis, provided your model file has been set up properly. The Section designator is optional; if it is left empty, the entire file will be included (provided it has no dependencies on needing a particular Section set up).
Building a Basic Script

When a model library has different sections and the ADS model library file is adapted using #define statements, a library Section can be selected. For example, to select the section NORMAL:

```c
$MODLIB1->parameterValue('adsSectionName', "NORMAL");
$MODLIB1->parameterValue('hspiceSectionName', "NORMAL");
$MODLIB1->parameterValue('spectreSectionName', "NORMAL");
```

Creating Instances

An instance in a design kit is typically a component definition that generally has similar netlist formats for each of the different simulators.

To start creating instances:

1. Create the instance handle.
2. Define the instance parameters.
3. Add the instance to the circuit.

For example, to create a circuit with two 1 volt DC voltage sources (V1 and V2) and a 10 ohm resistor (R1):

```c
$V1 = dKitInstance->new('V', 'V1');
$V1->parameterValue('Vdc', 1);
$Circuit->addInstance($V1);
$V2 = dKitInstance->new('V', 'V2');
$V2->parameterValue('Vdc', 1);
$Circuit->addInstance($V2);
$R1=dKitInstance->new('R', 'R1');
$R1->parameterValue('resistance', 10);
$Circuit->addInstance($R1);
```

Note that the parameter values should be in engineering notation if they are real numbers, and should not contain units. For example, a capacitor of 1nF would use:

```c
$C1=dKitInstance->new('C', 'C1');
$C1->parameterValue('capacitance', 1e-9);
$Circuit->addInstance($C1);
```

To know which parameters are defined for which instances refer to “Defining and Retrieving the Parameter Values” on page 4-25.
Connecting Instances

A circuit node is a connection of the terminals or pins between two or more instances. After all instances are added, you can connect them to each other using the `nodeName()` function supplied in the design kit model verification tool.

For example, to connect the internal node/pin/terminal `nplus` of Vds, the internal node/pin/terminal `n1` of R1:

```plaintext
$Vds->nodeName('nplus', 'node1');
$R1->nodeName('n1', 'node1');
```

Where `node1` is the name of the circuit node or connection point.

If you are working on a layout, you would probably use `trace1` in place of `node1`, where `trace1` would be the name of the trace connecting your components. For the design kit model verification tool, both nodes and traces are equivalent. However, the circuit node convention is generally used in the examples provided in this document.

For more information on node names for instances, refer to “Defining and Retrieving Node Names” on page 4-26.

Creating Analyses

Monte Carlo Analysis (MONTE) is supported by the design kit model verification tool; however, it is not a pure sweep as are the other analyses listed in this section. MONTE is more like a swept parameter. For more information, refer to “Monte Carlo Analysis” on page 4-29. The pure analyses that are currently supported by the design kit model verification tool are:

- AC (ac analysis)
- DC (dc analysis)
- SP (S-parameter analysis)
- NOISE (noise analysis)
- TRAN (transient analysis)

All supported pure analyses require one SWEEP parameter to be defined and consequently a SWEEPPLAN, with the exception of the transient analysis. If the default output from the simulators is not adequate, a OUTPUTPLAN can be added to these analyses to enumerate the desired outputs. If more parameters need to be swept, a SWEEP analysis can be added as well.
Building a Basic Script

Note OUTPUTPLANs added to a S-parameter analysis will be ignored.

The following example shows how to set up a DC analysis with two swept parameters; the DC voltage of the voltage source V1 and the temperature.

1. In this example, there are two parameters that must be swept. Therefore, two analysis handles are required.

   ```
   $SW1 = dKitAnalysis->new('SWEEP', 'SWEEP1');
   $DC1 = dKitAnalysis->new('DC', 'DC1');
   ```

2. The analyses need to be cascaded with the Sweep analysis in front. To ensure that the Sweep analysis is first, the analysis is stacked using the `addSubAnalysis()` function.

   ```
   $SW1->addSubAnalysis($DC1);
   ```

3. The defined Sweep parameters chosen in this example use the SWEEP analysis to sweep the DC voltage of V1, and the DC analysis to sweep the temperature.

   ```
   $SW1->setParameterValue('device', 'V1');
   $SW1->setParameterValue('parameter', 'Vdc');
   $DC1->setParameterValue('parameter', 'temp');
   ```

   The sweep definition could be reversed if needed. For global parameters such as temp and freq, you do not need to specify the device.

4. To setup the SweepPlans for simulation results for:

   - Fifty-one voltages of V1.
   - Vdc equally spaced between 0 to 2.5V.
   - Temperatures of -40, 27, and 155 degrees Celsius

   The following SWEEPPLANs are defined:

   ```
   $SWEEPPLAN1 = dKitAnalysis->new('SWEEPPLAN_LIN', 'SWL1');
   $SWEEPPLAN1->setParameterValue('start', 0);
   $SWEEPPLAN1->setParameterValue('stop', 2.5);
   $SWEEPPLAN1->setParameterValue('numPts', 51);
   $SW1->addSweepPlan($SWEEPPLAN1);
   $SWEEPPLAN2 = dKitAnalysis->new('SWEEPPLAN_PT', 'SWP1');
   $SWEEPPLAN2->setParameterValue('values', '-40 27 155');
   $DC1->addSweepPlan($SWEEPPLAN2);
   ```
5. If you defined a DC or AC analysis, you should also add an OutputPlan; otherwise there will not be any output from Hspice.

Note ADS and Spectre both generate a default OutputPlan if no plan is specified. For Noise and S-parameter analysis, a default outputplan is always added.

The most common output request is the value of the voltage at a certain node or trace. For this type of OutputPlan, you can use the OUTPUTPLAN_NODES default template. Using this template, you specify the nodes for which the voltage is desired as the value to the 'nodes' parameter. For example:

```plaintext
$OUTPUTNODES = dKitAnalysis->new('OUTPUTPLAN_NODES', "out1");
$OUTPUTNODES->parameterValue('nodes', "node1 node2");
$DC1->addOutputPlan($OUTPUTNODES);
```

To output the currents in a certain device, the default template OUTPUTPLAN_CURRENTS is provided. Using this template, you can specify the terminals of the devices for which you want the currents.

Note Currently ADS does not allow any selection of currents. However, ADS outputs the current through terminal 1 of voltage sources by default.

```plaintext
$OUTPUTCURRENTS = dKitAnalysis->new('OUTPUTPLAN_CURRENTS', "out2");
$OUTPUTCURRENTS->parameterValue('deviceTerminals', "V1:1 V2:1");
$DC1->addOutputPlan($OUTPUTCURRENTS);
```

For DC only, the device operating points (DOP) can be saved using the default OUTPUTPLAN_DOPS template. Using this template, you can specify the desired operating points as the value of its deviceParameters parameter. The names used to specify the parameters are the names of the design kit parameters (see “Understanding Parameters” on page 3-8).

```plaintext
$OUTPUTDOPS = dKitAnalysis->new('OUTPUTPLAN_DOPS', "out3");
$OUTPUTDOPS->parameterValue('deviceParameters', "V2:i");
$DC1->addOutputPlan($OUTPUTDOPS);
```
Building a Basic Script

Note The ADS simulator only allows you to select whether or not to save device operating points. So for ADS, you will get all device operating points or none.

6. To add the defined circuit analysis to the test circuit, use the `addAnalysis()` function as shown in this example.

   `$Circuit->addAnalysis($SW1);`

**Transient Analysis timeStepMethod Parameter**

There are three different values that the `timeStepMethod` parameter can be set to:

- fixed
- iteration
- trunc (default)

Note If you are performing a transient analysis with a parameter sweep, the `timeStepMethod` parameter must be set to fixed. For example:

   `$TRAN1->parameterValue('timeStepMethod', "fixed");`

Spectre only supports the truncation (trunc) `timeStepMethod`. Because of this, the `step` parameter uses the strobe capability of Spectre to emulate a fixed `timeStepMethod`.

**Defining the Simulators**

To define the simulators to run for ADS, Spectre, and Hspice, add the line:

   `$Circuit->simulate('ads', 'spectre', 'hspice');`

Your new test circuit script should now appear similar to the “Example Test Circuit Script” on page 3-19.
Example Test Circuit Script

#!/usr/bin/perl
BEGIN {
    if ($ENV{DKITVERIFICATION} eq "")
        {
            if ($ENV{HPEESOF_DIR} eq "")
            {
                print "\nPlease set environment variable DKITVERIFICATION\nto point to the design kit model verification installation directory\n\n";
                exit 1;
            } else
            {
                print "$ENV{DKITVERIFICATION} = \n\n";
            } $myLibPath = "$ENV{DKITVERIFICATION}/perl/lib";
        } if (! -d $myLibPath)
            {
                if ($ENV{DKITVERIFICATION} eq "$ENV{HPEESOF_DIR}/design_kit/verification")
                {
                    if (! -d "$ENV{HPEESOF_DIR}/design_kit/verification")
                    {

### End of script
```

Running the Test Circuit Script

If you did not initialize the template or parameter databases yet, i.e. you do not have a `dKitTemplateDB.pl` or `dKitParameterDB.pl` file in your working directory, you need to do it now.

To initialize the template database:

   `dKitTemplateCreate.pl`

To initialize the Parameter database:

   `dKitParameterCreate.pl`

Some more advanced default templates use subcircuits, (see Chapter 4, Building an Advanced Script). If these templates are used within your circuit, you need to initialize the subcircuit database:

   `dKitSubcircuitCreate.pl`

Alternatively, all of the above modules can be initialized at the same time using:

   `dKitSetupWork.pl`

If you run the “Example Test Circuit Script” on page 3-19, your results should appear in a dataset (`<name>.ds`) format.

You may receive several warning messages after running your script.

   Please define parameter `<param>` using ...

This is to inform you that the dKit specific parameter `<param>` could not be translated to a simulator specific parameter, but kept its dKit Specific name. You may also have gotten the warning:

   Please define a parameter using ... so that the `<dialect>` parameter `<param>` ...

This means that the `<dialect>` simulator specific parameter `<param>` could not be translated to a result name, but kept its simulator specific name. In this case you can freely choose the name of the dKit parameter.
If you want to list an overview of which parameters were not translated to a result name, add the following line to the end of your TEST CIRCUIT script after the line
$Circuit->simulate('ads', 'spectre', 'hspice');
   print dKitParameter->listMissingParameterDefinitions;

---

**Viewing Your Results in a Data Display**

Simulation results are stored in datasets (*.ds) and citifiles (*.cti). To view your results in an ADS Data Display:

1. Launch ADS and create a new project `<adsproject>` if necessary.
2. Copy all of your datasets to your ADS project’s data directory (`<adsproject>/data`).
3. Launch the ADS Data Display server from your ADS window. From the ADS Main window, choose *Window > New Data Display*.
4. Create a template to view your results. For more information, refer to “Using a Template in Your Display” in the ADS “Data Display” documentation.
5. Select the dataset to view the results. If your parameters have been defined correctly, you should be able to use the `<dataset> <simulator> <parameter>` to access the different results for the different simulators, with `<simulator>` equal to `ads_sim`, `spectre_sim` or `hspice_sim`.

For more information on datasets (*.ds) and citifiles (*.cti), refer to Chapter 7 of the ADS “Circuit Simulation” manual.

For more information on simulation results, refer to Chapter 5, Comparing Simulation Results.
Chapter 4: Building an Advanced Script

This chapter first gives a more thorough description (function level) of the different modules which make up the design kit model verification tool. This information is required before you can proceed with creating more advanced scripts.

Module Reference

The perl module files (*.pm) contain the functions used for creating the individual perl scripts. The different modules used by the design kit model verification tool are shown here.

- “Template Module” on page 4-3
- “Parameter Module” on page 4-9
- “Circuit Module” on page 4-13
- “Instance and Analysis Modules” on page 4-24
- “Results Module” on page 4-33

For a summary of all template functions provided in the perl modules and their basic functionality, refer to “Design Kit Model Verification Tool Perl Modules” on page 4-38.

Using the Module Debug Facility

All modules have a debug facility which can be turned on using the command:

```
dKit<module>->debug(<level>);
```

A `<level>` value of 0 turns debugging off. The higher the value of `<level>`, the more information you will receive. The information you receive will depend on the design kit `<module>` you are debugging.

The value of `<module>` can be Template, Parameter, Instance, Analysis or Circuit. E.g. dKitCircuit->debug(1); will not delete the intermediate files (e.g. netlist files).

Currently, the highest debug value is 100; however, not all intermediate values are used.
Quoting your string-variables

Within the perl scripts, it is required to use vertical quoted strings ('<string>' or "<string>") wherever the chosen value happens to be a perl command, otherwise your script will not run correctly. Within the perl scripts, it is highly recommended that you quote all strings to reduce the possibility of generating errors.

---

**Note**  
In perl, single quotes ('<string>') represent text as is, with no variable substitution. Double quotes (“<string>”) perform variable substitution. For example, "$myVar" will be substituted by its value if it is in double quotes, while '$myVar' will just be equal to $myVar if it is in single quotes.

Open quotes ('<string>' or “<string>”) are not allowed for quoting strings in perl and vertical quotes ('<string>' or "<string>") should be used instead. While there is a very subtle difference in the appearance of the two styles, perl will not accept open quotes.
Template Module

A template can be considered as the set of rules for how to translate the item defined using the dKit* commands to the simulator netlist dialect (See “Understanding Templates” on page 3-4).

The template module (dKitTemplate.pm) contains functions to perform the following operations:

- “Creating a New Template Handle” on page 4-4
- “Retrieving a Handle of an Existing Template” on page 4-4
- “Documenting a Template” on page 4-4
- “Retrieving the Template Documentation” on page 4-4
- “Setting the Item Name Prefix” on page 4-4
- “Defining the Translation Rules” on page 4-5
- “Defining Template Parameters and Nodes/Pins” on page 4-7
- “Setting a Default Template Parameter Value” on page 4-7
- “Retrieving the Default Template Parameter Value” on page 4-7
- “Displaying the Defined Templates” on page 4-7
- “Saving the Template Definitions to Allow Fast Access” on page 4-8
Building an Advanced Script

Creating a New Template Handle
To create a handle to a new template, use the function:

```perl
$Template = dKitTemplate->new(''<templateName>'');
```

Note that `<templateName>` should be a unique name. If a template is redefined using an existing template name, an error will be generated.

Retrieving a Handle of an Existing Template
To retrieve a handle of an existing template use the function:

```perl
$Template = dKitTemplate->getTemplate(''<templateName>'');
```

$Template is undefined if the template with `<templateName>` does not exist.

Documenting a Template
To document your template, use the function:

```perl
$Template->description("<templateDescriptionText>");
```

Where `<templateDescriptionText>` is the text describing the template.

Retrieving the Template Documentation
To get the documentation of a template, use the function:

```perl
$myDescription = $Template->description();
```

$myDescription will then contain the string describing the template.

Setting the Item Name Prefix
Hspice requires that the name of instances of certain components start with a predefined prefix. This is also implemented in the dKit verification syntax by the function:

```perl
$Template->requiredPrefix("<prefix>");
```

For example, Hspice uses the prefix "r" to designate a resistor. Therefore, defining the "r" prefix for a resistor (whose Template Handle is $R) would be done by:

```perl
$R->requiredPrefix("r");
```
The prefixes are case insensitive, this means that in the example above, resistor names can start with R or r.

**Note** All names are lowercase in the HSpice results file. If you require an HSpice simulation and you want your results dataset to reflect the simulator name, your devices/nodes should only contain lower case. For more information, refer to "Viewing Your Results in a Data Display" on page 3-23.

### Defining the Translation Rules

To define how your template will be translated for each dialect, use the `netlistInstanceTemplate` function:

```perl
$Template->netlistInstanceTemplate("<dialect>", "<netlistFormat>");
```

where `<dialect>` is the supported simulator dialect and `<netlistFormat>` is the defined structure for the netlist. An example for a standard resistor is shown in Table 4-1.

**Table 4-1. Example Template for a Resistor**

```perl
$R = dKitTemplate->new('R');
$R->description("Resistor");
$R->requiredPrefix('r');
$R->netlistInstanceTemplate('hspice', '#instanceName %n1 %n2 <modelName> R=<resistance> [[TC1=<tempCoef1>]] [[TC2=<tempCoef2>]] [[SCALE=<scale>]] [[M=<multiplicity>]] [[AC=<acResistance>]] [[DTEMP=<dtemp>]] [[L=<length>]] [[W=<width>]] [[C=<capacitanceN2Bulk>]]');
$R->netlistInstanceTemplate('ads', 'R:#instanceName %n1 %n2 R=<resistance> [[Temp=<temp>]] [[Tnom=<tnom>]] [[TC1=<tempCoef1>]] [[TC2=<tempCoef2>]] [[Noise=<noise>]] [[M=<multiplicity>]]');
$R->netlistInstanceTemplate('spectre', '#instanceName %n1 %n2 resistor r=<resistance> [[trise=<dtemp>]] [[tc1=<tempCoef1>]] [[tc2=<tempCoef2>]] [[isnoisy=<noise>]] [[m=<multiplicity>]]');
```

When defining the netlist format, the following special directives are available:

- **#function**: Calls the internally defined function or hook. Currently, `#instanceName` is the only function supported. `#instanceName` returns the name of the item. The other `#names` you will find in the `dKitTemplateCreate.pl` file are hooks, i.e. they direct the netlist function of the Circuit Module to follow a different path in the code. So you need to be a perl expert to modify those within the perl modules of the design kit model verification tool distribution. For
Building an Advanced Script

Information on modifying the source code, refer to “Modifying the Source Code” on page 2-5.

• %node: Adds the internal node/pin node to this item, e.g. %n1

• <name>: Adds name as a template parameter. If you assign a value to this parameter when defining the item that uses this template, <name> will be replaced by its value in the netlist.

• ~eval(text)end: Means that the text, after all parameters have been substituted by their values, will be passed to the perl eval function. In this way you can do operations on the parameters before they are substituted in the netlist.

For example, observe the following netlist definition.

```perl
$T->netlistInstanceTemplate(ads, 'TLIN4:#instanceName %in %refin %out %refout [[Z=<Z0>]] [[F=<frequency>]] [[E=~eval(<electricalLength> * 360);end]]');
```

The ADS parameter E equals 360 times the design kit parameter electricalLength. This is a simple example, actually you can include whole perl scripts. If you need additional variables in the text, be sure to use the my declarator, otherwise it will not work! This is a perl specific declarator to say variables are local.

The previous example with a more explicit definition would be:

```perl
$T->netlistInstanceTemplate(ads, 'TLIN4:#instanceName %in %refin %out %refout [[Z=<Z0>]] [[F=<frequency>]] [[E=~eval(my $electricalLength ="<electricalLength>"; if ($electricalLength ne ")") {return $electricalLength* 360;} else {return ");end]))']);
```

• [[ test ]]: Means what is between the [ ] is optional, and will not be netlisted for the item using this netlist unless all parameters which are listed between the [ ] and are not part of an ~eval(text)end expression are defined AND all top-level ~eval(text)end evaluations return non-empty strings.

If you do not put a parameter definition between [[ ]] then this parameter is required, and you will get an error if you try to netlist an item using this template which does not have a value defined for this parameter. For example, the resistance shown in the resistor example of Table 4-1 uses R=<resistance>.

If an ~eval(text)end expression is not between [[ ]] then this expression is required, and you will get an error if the top-level ~eval(text)end evaluation
returns an empty string. It is not an error for a nested ~eval(text)end
evaluation to return an empty string.

You can find more examples of templates in the dKitTemplateCreate.pl
file.

**Defining Template Parameters and Nodes/Pins**

While parsing the translation rules, the internal nodes/pins and parameters are
automatically added to the template. If you want to add additional nodes and
parameters, you can use the functions:

```
$Template->addNode("nodeName");
$Template->addParameter("parameterName");
```

**Setting a Default Template Parameter Value**

A parameter of a template can be given a default value, which will be netlisted if the
item using this template does not redefine the parameter. By giving a parameter a
default value, you make it a required parameter, which will be netlisted always.

You assign a default value by means of the function

```
$Template->parameterValue("<parameter>", "<value>");
```

The parameter needs to be defined otherwise this function will return an error.

**Retrieving the Default Template Parameter Value**

You retrieve the default template parameter value using the function:

```
$myDefaultValue = $Template->parameterValue('<parameter>');
```

If no default value is assigned, an empty string is returned.

**Displaying the Defined Templates**

If you want to display which templates are currently defined, you can use one of the
following functions at any time with the perl template definition script:

```
dKitTemplate->dumpTemplates;
```

or

```
print dKitTemplate->templates2perl;
```
Building an Advanced Script

Saving the Template Definitions to Allow Fast Access

For faster access, it is better to have your templates stored in a hash table than having to process them from a file. Therefore, use the function,

    dKitTemplate->createTemplateDatabaseFile;

to translate your template definitions into a hash table and add them to the module dKitTemplate.pm in your working directory.

It is a good practice to keep the definition of your templates in a separate file. Optimally - without being annoyed by the error template already defined - use the example shown in Table 4-2 for constructing the template definition perl script file.

<table>
<thead>
<tr>
<th>Table 4-2. Example Template Definition Script</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#!&lt;myPath2Perl&gt;/perl</code></td>
</tr>
<tr>

<tr>
<td><code>### end of template creation script file</code></td>
</tr>
</tbody>
</table>
Parameter Module

The parameter module is used to map different variable names used by the different simulators for the same parameter. For example, the dc voltage of a voltage source is called:

- \texttt{Vdc} for ADS
- \texttt{dc} for Spectre and Hspice.

To avoid conflicts between variable names, you can set up parameter mappings that define the parameter name (name used in the design kit model verification tool), the dialect name (the name used by the simulator), and the result name (the name used when processing the results). See “Creating a Parameter Handle” on page 4-10.

There are several dialects currently supported by the design kit model verification tool. For information on supported dialects, refer to “Supported Simulators” on page 2-1.

The parameter module (dKitParameter.pm) contains functions to perform the following operations:

- “Creating a Parameter Handle” on page 4-10
- “Documenting a Parameter” on page 4-10
- “Retrieving the Parameter Documentation” on page 4-10
- “Defining the Dialect Name for a Parameter” on page 4-10
- “Defining the Result Name for a Parameter” on page 4-11
- “Displaying the Defined Parameters” on page 4-11
- “Saving the Parameter Definitions to Allow Fast Access” on page 4-12
- “List All Missing Parameter Definitions” on page 4-12
Creating a Parameter Handle

To create a handle to a new parameter, use the function:

```perl
$Parameter = dKitParameter->new( '<parameterName>' );
```

Where `<parameterName>` is the name to be used in the verification tool Perl scripts.

Example:

Using the following example to create a parameter which will define the dc voltage of a voltage source:

```perl
$VDC = dKitParameter->new('Vdc');
```

you will have to use "Vdc" as the value of the "parameter" parameter of a Sweep Analysis if you want to sweep the dc voltage of a voltage source.

Documenting a Parameter

To document your template, use the function:

```perl
$Parameter->description( "<parameterDescriptionText>" );
```

Where `<parameterDescriptionText>` is the text describing the parameter.

Example:

```perl
$VDC->description("DC Voltage");
```

Recovering the Parameter Documentation

To retrieve the documentation of a parameter, use the function:

```perl
$myDescription = $Parameter->description;
```

Defining the Dialect Name for a Parameter

The different dialect names for the parameter are added by using the function:

```perl
$Parameter ->dialectReference( '<dialect>', '<dialectParameterName>' );
```

Example:

```perl
$VDC->dialectReference('spectre', 'dc');
$VDC->dialectReference('hspice', 'dc');
$VDC->dialectReference('ads', 'Vdc');
```
Defining the Result Name for a Parameter

To define the result name for the parameter use the function:

```perl
$Parameter->resultName("<resultName>");
```

Because Hspice result files use lowercase, it is advised to use all lowercase resultNames if you want to make comparisons with Hspice results.

**Note** The `resultName` names should be chosen in order that `$parameter($dialect)->resultName` is unique. For example, `$VDC(hspice)->dc`.

**Examples**

```perl
$VDC = dKitParameter->new("Vdc");
$IDC = dKitParameter->new("Idc");
$IDC->dialectReference('hspice', 'dc');
$VDC->dialectReference('hspice', 'dc');
$IDC->dialectReference('ads', 'Idc');
$VDC->dialectReference('ads', 'Vdc');
```

Using the following `resultNames`

```perl
$IDC->resultName("idc");
$VDC->resultName("vdc");
```

would create ambiguity, because both have the Hspice reference 'dc'. I.e. in the results file you will find dc, but you do not know whether it stems from IDC being translated to DC or VDS being translated to DC. Instead, use:

```perl
$IDC->resultName("dc");
$VDC->resultName("dc");
```

Displaying the Defined Parameters

To display the parameters which are currently defined you can use one of the following functions at any time with the perl parameter definition script

```perl
dKitParameter->dumpDKitXrefs;
```

or

```perl
print dKitParameter->dKitXrefs2perl;
```
Building an Advanced Script

**Saving the Parameter Definitions to Allow Fast Access**

For faster access, it is better to have your parameters stored in a hash table than having to read them from a file. Therefore, use the function:

```perl
dKitParameter->createParameterDatabaseFile;
```

to translate your parameter definitions into a hash table and add them to the module dKitParameter.pm in your working directory.

**List All Missing Parameter Definitions**

To list all missing parameter definitions, use the following function after the circuit is simulated:

```perl
dKitParameter->listMissingParameterDefinitions;
```
Circuit Module

To initialize the circuit module, add the following line before using any functions to define your test circuit.

use dKitCircuit;

The circuit module (dKitCircuit.pm) contains functions to perform the following operations:

- "Creating a New Circuit Handle" on page 4-15
- "Setting the Circuit Name" on page 4-15
- "Adding Simulator Options" on page 4-15
- "Removing Simulator Options" on page 4-15
- "Retrieving the list of Simulator Option Handles" on page 4-16
- "Retrieving a Specific Simulator Option Handle" on page 4-16
- "Adding a Path to a Model Library" on page 4-16
- "Removing a Path to a Model Library" on page 4-16
- "Retrieving the list of Model Library Path Handles" on page 4-16
- "Retrieving a Specific Model Library Path Handle" on page 4-16
- "Adding Components/Instances" on page 4-17
- "Removing Components/Instances" on page 4-17
- "Retrieving the List of Instance Handles" on page 4-17
- "Retrieving a Specific Instance Handle" on page 4-17
- "Adding Analyses" on page 4-18
- "Removing Analyses" on page 4-18
- "Retrieving the List of Analysis Handles" on page 4-18
- "Retrieving a Specific Analysis Handle" on page 4-18
- "Retrieving an Analysis Handle from within the Analysis Hierarchy" on page 4-18
- "Retrieving a Sweep Plan Handle from within the Analysis Hierarchy" on page 4-19
Building an Advanced Script

- “Retrieving a Output Plan Handle from within the Analysis Hierarchy” on page 4-19
- “Simulating a Circuit” on page 4-19

For dealing with subcircuits the following functions are available:

- “Defining a Subcircuit” on page 4-20
- “Creating the Subcircuit Database File” on page 4-20
- “Creating a new Circuit by Cloning a Subcircuit” on page 4-20
- “Defining and Modifying Circuit or Subcircuit Parameters” on page 4-21
- “Defining a Template using a Subcircuit” on page 4-21
- “Defining a Subcircuit and its Template” on page 4-22

For the more advanced users, additional functions are available to perform the following operations:

- “Adding a Startdeck and Enddeck Card” on page 4-22
- “Creating the Simulator Netlist” on page 4-22
- “Simulating a Circuit from a Netlist” on page 4-23
- “Freeing Memory Occupied by the Simulation Results” on page 4-23
Creating a New Circuit Handle

To create a new circuit, use the function:

```perl
$Circuit = dKitCircuit->new("<circuitName>");
```

See also “Setting the Circuit Name” on page 4-15.

Setting the Circuit Name

You set the circuitName using the function:

```perl
$Circuit->circuitName("<circuitName>");
```

Where `<circuitName>` determines where all data will be stored. If `<circuitName>` contains forward slashes (/), all intermediate files, including the simulator netlists, will be placed in a subdirectory. See also “Simulating a Circuit” on page 4-19.

Adding Simulator Options

There are some default options given for the different simulators if you do not specify any options. However, if you specify one option for a given simulator, all other default options will be erased.

The following options MUST be set for the verification tool to run correctly:

- `spectre`: `rawfmt=psfascii`
- `ADS`: `UseNutmegFormat=no ASCII_Rawfile=yes`

and therefore they will ALWAYS be added to the netlist.

To add simulator options, use the function:

```perl
$Circuit->addSimulatorOption($OPTION);
```

where `$OPTION` is a reference to an instance. See “Instance and Analysis Modules” on page 4-24.

Removing Simulator Options

To remove a previously added simulator option from your circuit, use the function:

```perl
$Circuit->removeSimulatorOption($Instance);
```
Building an Advanced Script

**Retrieving the list of Simulator Option Handles**
To retrieve the handles of the local simulator options within the Circuit $CIRCUIT, use the function:

```perl
my @handles = $CIRCUIT->getSimulatorOptions;
```

**Retrieving a Specific Simulator Option Handle**
To retrieve the handle of a local simulator option named "name" within the Circuit $CIRCUIT, use the function:

```perl
my $handle = $CIRCUIT->getLocalSimulatorOption("name");
```

**Adding a Path to a Model Library**
To add the path to a modelLibrary, use the function:

```perl
$Circuit->addModelLibrary($MODELLIBRARY);
```
where $MODELLIBRARY is a reference to an instance. See “Instance and Analysis Modules” on page 4-24.

**Removing a Path to a Model Library**
To remove a previously added path to a modelLibrary from your circuit, use the function:

```perl
$Circuit->removeModelLibrary($Instance);
```

**Retrieving the list of Model Library Path Handles**
To retrieve the handles of the local model library paths within the Circuit $CIRCUIT, use the function:

```perl
my @handles = $CIRCUIT->getModelLibraries;
```

**Retrieving a Specific Model Library Path Handle**
To retrieve the handle of a local model library path named "name" within the Circuit $CIRCUIT, use the function:

```perl
my $handle = $CIRCUIT->getLocalModelLibrary("name");
```
Adding Components/Instances

To add components or netlist parameters, use the function:

```perl
$Circuit->addInstance($Instance);
```

where $Instance is a reference to an instance. See “Instance and Analysis Modules” on page 4-24.

The order in which the instances are added will also be the order in which the instances will be netlisted.

This is for instance important for PARAMETER instances, because in Hspice parameter instances defining an equation should only be netlisted (added) after the elements or parameters within the equation are defined.

If you have the following definition:

```perl
$P1 = dKitInstance->new('PARAMETER', 'rsq');
$P1->parameterValue('value', 1);
$P2 = dKitInstance->new('PARAMETER', 'r_l');
$P2->parameterValue('value', 'rsq*r_w');
$P3 = dKitInstance->new(PARAMETER, 'r_w');
$P3->parameterValue('value',1.34e-6);
```

then, $P2 should be added (using $Circuit->addInstance) AFTER $P1 AND $P3 have been added.

Removing Components/Instances

To remove a previously added instance from your circuit, use the function:

```perl
$Circuit->removeInstance($Instance);
```

Retrieving the List of Instance Handles

To retrieve the handles of the local instances within the Circuit $CIRCUIT, use the function:

```perl
my @handles = $CIRCUIT->getInstances;
```

Retrieving a Specific Instance Handle

To retrieve the handle of a local instance named "name" within the Circuit $CIRCUIT, use the function:
Building an Advanced Script

```
my $handle = $CIRCUIT->getLocalInstance("name");
```

Adding Analyses

To add analyses, use the function:

```
$Circuit->addAnalysis($Analysis);
```

where $Analysis is a reference to an analysis. See instance/analysis module.

---

**Note** Currently only one analysis can be added to a circuit.

---

Removing Analyses

To remove a previously added analysis from your circuit, use the function:

```
$Circuit->removeAnalysis($Instance);
```

Retrieving the List of Analysis Handles

To retrieve the handles of the local analysis within the Circuit $CIRCUIT, use the function:

```
my @handles = $CIRCUIT->getAnalyses;
```

Retrieving a Specific Analysis Handle

To retrieve the handle of a local analysis named "name" within the Circuit $CIRCUIT, use the function:

```
my $handle = $CIRCUIT->getLocalAnalysis("name");
```

Retrieving an Analysis Handle from within the Analysis Hierarchy

To retrieve an analysis with a given name from the circuit analyses, including its subanalyses, use the function:

```
my $handle = $CircuitHandle->getFlattenedAnalysis("name");
```
Because the handle lost all of its hierarchical information, it should ONLY be used to change the values of the parameters of the analysis.

Retrieving a Sweep Plan Handle from within the Analysis Hierarchy

To retrieve a sweep plan with a given name from the circuit analyses, including its subanalyses, use the function:

```perl
my $handle = $CircuitHandle->getFlattenedSweepPlan("name");
```

Because the handle lost all of its hierarchical information, it should ONLY be used to change the values of the parameters of the sweep plan.

Retrieving a Output Plan Handle from within the Analysis Hierarchy

To retrieve an output plan with a given name from the circuit analyses, including its subanalyses, use the function:

```perl
my $handle = $CircuitHandle->getFlattenedOutputPlan("name");
```

Because the handle lost all of its hierarchical information, it should ONLY be used to change the values of the parameters of the output plan.

Simulating a Circuit

To simulate a circuit after it is defined, issue the command

```perl
$Circuit->simulate("<dialect1>", "<dialect2>", "<dialect3>", "...");
```

The currently supported dialects are defined in “Supported Simulators” on page 2-1.

The output of the simulation function creates a dataset (<circuitNameForDs>.ds) in your working directory. The <circuitNameForDs> is the name you give to your circuit using the function:

```perl
$Circuit->circuitName("<circuitName>");
```

where all forward slashes (/) are replaced by underscores (_).

It also creates a cti file (<circuitNameForCti>.cti). This will be placed in the correct subdirectories if <circuitNameForCti> contains forward slashes (/).
Building an Advanced Script

If you only supply one dialect to the simulate function, _<dialect>_ will be appended to the <circuitName> when creating <circuitNameForCti> and <circuitNameForDs>.

All intermediate files, including the simulator netlists, will be removed unless you set the circuit level debugging to '1' or higher using the debug command:

```perl
dKitCircuit->debug(<level>);
```

Defining a Subcircuit

Once a circuit is defined, it can be cataloged as a subcircuit for subsequent use by means of the function:

```perl
$Circuit->addToSubcircuits([nodeList, parameterList [,optionalParameterList]]);
```

Where:

- nodeList = The list of node names of this subcircuit (e.g. ['n1', 'n2', ...]).
- requiredParameterList = A list with the required parameters and their initial values (e.g. ['l', 'w=1']).
- optionalParameterList = A list with the optional parameters and their initial values (e.g. []).

**Note** Optional parameters, when added, need to have an initial value, otherwise the simulation will not be successful.

Creating the Subcircuit Database File

To store all currently defined subcircuits within the database file, use the function:

```perl
$Circuit->createSubcircuitDatabaseFile;
```

This will store the currently defined subcircuits in the dKitSubcircuitDB.pl file.

Creating a new Circuit by Cloning a Subcircuit

A completely new circuit can be created from a subcircuit, with the command:

```perl
my $Circuit = dKitCircuit->clone("<subcircuitName>");
```
Its parameters can then be altered as described in “Defining and Modifying Circuit or Subcircuit Parameters” on page 4-21. Or handles to its items can be retrieved which can be used to modify their parameters as described in “Defining and Retrieving the Parameter Values” on page 4-25 within the Instance/Analysis Module. After which a simulation can be performed as described in “Simulating a Circuit” on page 4-19.

**Defining and Modifying Circuit or Subcircuit Parameters**

For subcircuits or circuits created by cloning a subcircuit, it might be necessary to modify circuit parameters.

To get the value of a circuitParameter, use:

```
$Circuit->parameterValue("<parameterName>");
```

To set the value of a circuitParameter, use:

```
$Circuit->setParameter("<parameterName>", "<value>");
```

**Note** It is not possible to assign lists or arrays to a parameter, only simple values or expressions can be assigned.

The parameter needs to be defined otherwise you will get an error. To define a parameter, you can use the function:

```
$Circuit->addParameter("<parameterName>");
```

**Defining a Template using a Subcircuit**

To define a template, which can be used as an instance in other circuits, for a subcircuit only containing instances, use the function:

```
$Circuit->createSubcircuitTemplateOnly("<templateName>", nodeList, requiredParameterList, optionalParameterList);
```

Where:

- `<templateName>` = The name of the template.
- `nodeList` = The list of node names (e.g. ['n1', 'n2', ...]).
- `requiredParameterList` = A list with the required parameters and their initial values (e.g. ['l=1e-3', 'w']).
- `optionalParameterList` = A list with the required parameters and their initial values (e.g. ['l=1e-3', 'w']).
Building an Advanced Script

optionalParameterList = A list with the optional parameters and their initial values (e.g. []).

To save this template definition in the template database, use:

dKitTemplate->createTemplateDatabaseFile;

as described in “Saving the Template Definitions to Allow Fast Access” on page 4-8.

Defining a Subcircuit and its Template

The functionality of "Defining a Subcircuit" and "Defining a Template using a Subcircuit" is for the ease of use combined into one function call:

$Circuit->createTemplateANDaddToSubcircuits("<templateName>", nodeList, requiredParameterList, optionalParameterList);

Adding a Startdeck and Enddeck Card

There is also a possibility to add a startDeckCard and endDackCard. This is done by changing the defaults for the template CIRCUITSTARTDECKCARD and CIRCUITENDDECKCARD respectively. By default a Spectre file will start with 'simulator lang=spectre', and Hspice will end a file with .end.

Creating the Simulator Netlist

Normally the netlist is automatically created when you simulate your test circuit. However, if you want to have access to the netlist without doing a simulation, you can use the command:

$myNetlist = $Circuit->netlist("<dialect>");

which will assign the netlist to the perl variable $myNetlist, or:

$Circuit->netlist("<dialect>", "<fileName>");

which will write the netlist to the file <fileName>. If you want to simulate the netlist after editing, refer to “Simulating a Circuit from a Netlist” on page 4-23 for information on choosing the fileName.
Note If the `<fileName>` is equal to the `<circuitName>` with the default dialect extension, that file will be removed if the same perl script also performs a simulation and is using circuit debug level 0.

Simulating a Circuit from a Netlist

To run a simulation given a netlist file, issue the command:

```perl
dKitCircuit->simulate("<netlist1>", "<netlist2>", ...);
```

where `<netlist1>`, `<netlist2>` are the names of the netlist files. The suffixes of the netlists will determine which simulator will be called. They are defined by the parameters `<dialect>-NetlistSuffix` of the default Template `CIRCUITNETLISTNAME`. They are `.hsp` for Hspice, `.ckt` for the ADS circuit simulator, `.scs` for Spectre. If the basenames (i.e. the name without the suffix) are equal a combined dataset will be created, just like if you would have used the command:

```perl
$Circuit->simulate("<dialect1>", "<dialect2>", ...);
```

See “Simulating a Circuit” on page 4-19.

Freeing Memory Occupied by the Simulation Results

When the simulation completes, the simulation results are normally kept in memory in order to have fast access to the results when additional statistical operations need to be performed. However, for large circuits the amount of data kept might be substantial and when simulating a lot of circuits from within the same perl file you might encounter an out of memory error during the execution of the perl test circuit script. To prevent this from happening you can issue the command:

```perl
$Circuit->deleteResultsFromMemory();
```

when you do not need the simulation results any more for the circuit. It will free up the memory taken by the results so it can be used by other simulations.

Note Do not change the name of the circuit between the call to simulate and deleteResultsFromMemory, or the deleteResultsFromMemory function will have no effect.
Instance and Analysis Modules

Instances and Analyses are very similar (they are both defined using templates); however, they are put into separate modules because:

- Instances (components/options/...) have a very similar netlist format for the different simulators, Analyses do not.
- Analyses can include subanalyses, Instances cannot include subinstances. A subcircuit is just an instance.

The following operations can be performed by both modules:

- “Creating a New Item Handle” on page 4-25
- “Viewing the Template Definition” on page 4-25
- “Defining and Retrieving the Parameter Values” on page 4-25

The instance module (dKitInstance.pm) contains functions to perform the following instance specific operations:

- “Retrieving the InstanceName” on page 4-26
- “Defining and Retrieving Node Names” on page 4-26

The analysis module (dKitAnalysis.pm) contains functions to perform the following analysis specific operations:

- “Retrieving the AnalysisName” on page 4-26
- “Adding a Sweepplan” on page 4-26
- “Retrieving the List of Sweep Plan Handles” on page 4-27
- “Removing a Sweepplan” on page 4-27
- “Adding an OutputPlan” on page 4-27
- “Retrieving the List of Output Plan Handles” on page 4-28
- “Removing an OutputPlan” on page 4-28
- “Adding a Sub Analysis” on page 4-28
- “Retrieving the List of Sub Analysis Handles” on page 4-28
- “Removing a Sub Analysis” on page 4-28
- “Scale/Offset a Sweep Parameter” on page 4-28
Creating a New Item Handle

An instance is created using the command:

```perl
$InstanceHandle = dKitInstance->new("templateName", "instanceName");
```

Note that the same name cannot be used for two different instances.

An analysis is created using the command:

```perl
$AnalysisHandle = dKitAnalysis->new("templateName", "analysisName");
```

Note that the same name cannot be used for two different analyses.

For a list of standard supported instances and analysis, refer to Appendix A, Template List.

Viewing the Template Definition

To retrieve a description of the template definition use:

```perl
$myTemplateDef = $InstanceOrAnalysisHandle->template->dump2str;
```

To print it to the screen use the standard perl print function, e.g.

```perl
print "$myTemplateDef\n";
```

This will cause the template definition to be printed to the terminal window upon completion of the script.

Alternatively you could use the method described in “Displaying the Defined Templates” on page 4-7, or the Template reference table in Appendix A, Template List if it is a standard template.

Defining and Retrieving the Parameter Values

Once an instance or analysis is created, the value of the parameters which are defined by the template need to be set. To set a parameter value, use the command:

```perl
$InstanceOrAnalysisHandle->parameterValue("parameterName", "value");
```

If value is numeric, it should be in engineering or floating notation (1e-3 or 0.001) without units. For example, the value for the capacitance of a 1nF capacitor should be specified as 1e-9.
Building an Advanced Script

To retrieve the value of a parameter use:

```
$myValue = $InstanceOrAnalysisHandle->parameterValue("parameterName");
```

To know which parameters are available, see “Viewing the Template Definition” on page 4-25.

Retrieving the InstanceName

The instanceName of an instance can be retrieved using:

```
$myName = $InstanceHandle->instanceName;
```

Defining and Retrieving Node Names

If an instance has nodes, which is the case for all components, then you must define the node names using:

```
$Instance->nodeName("internalName", "circuitNodeName");
```

This assigns the name of the circuitNode to the internal instance node. For more information, refer to “Connecting Instances” on page 3-15.

To retrieve the name of the circuitNode use the command:

```
$myCircuitNode = $Instance->nodeName("internalName");
```

For information on knowing which internal nodes are defined, refer to “Viewing the Template Definition” on page 4-25.

Retrieving the AnalysisName

The analysisName of an analysis can be retrieved using:

```
$myName = $AnalysisHandle->analysisName;
```

Adding a Sweepplan

To add a sweepplan to an analysis use:

```
$AnalysisHandle->addSweepPlan($SweepPlanHandle);
```
Sweepplans are expected for all analyses with the exception of TRAN and MONTE.

Sweepplans are a special type of analyses. They are created using:

```perl
$SweepplanHandle = dKitAnalysis->new("sweepplanTemplateName", "sweepplanName");
```

For a list of standard supported sweepplans, refer to “Sweepplan Templates” on page A-7.

### Retrieving the List of Sweep Plan Handles

To retrieve the handles of the local sweep plans within the Analysis $AnalysisHandle, use the function:

```perl
my @handles = $AnalysisHandle->getSweepPlans;
```

### Removing a Sweepplan

To remove a sweepplan from an analysis use:

```perl
$AnalysisHandle->removeSweepPlan($SweepplanHandle);
```

### Adding an OutputPlan

To add an outputplan to an analysis use:

```perl
$AnalysisHandle->addOutputPlan($OutputplanHandle);
```

#### Note
Multiple outputplans can be added to an analysis.

Outputplans are a special type of analyses. They are created using:

```perl
$OutputplanHandle = dKitAnalysis->new("outputplanTemplateName", "outputplanName");
```

For a list of standard supported outputplans, refer to “Outputplan Templates” on page A-5.
Building an Advanced Script

**Retrieving the List of Output Plan Handles**

To retrieve the handles of the local output plans within the Analysis $AnalysisHandle, use the function:

```perl
my @handles = $AnalysisHandle->getOutputPlans;
```

**Removing an OutputPlan**

To remove an outputplan from an analysis use:

```perl
$AnalysisHandle->removeOutputPlan($OutputplanHandle);
```

**Adding a Sub Analysis**

To add a subanalysis to a sweep analysis use:

```perl
$AnalysisHandle->addSubAnalysis($SubAnalysisHandle);
```

---

**Note**  
Currently only one subanalysis / analysis is supported.

---

**Retrieving the List of Sub Analysis Handles**

To retrieve the handles of the local sub analyses within the Analysis $AnalysisHandle, use the function:

```perl
my @handles = $AnalysisHandle->getSubAnalyses;
```

**Removing a Sub Analysis**

To remove a sub analysis from a sweep analysis use:

```perl
$AnalysisHandle->removeSubAnalysis($SubAnalysisHandle);
```

**Scale/Offset a Sweep Parameter**

There is no specific analysis module function to scale/offset a specific sweep parameter, but the sweepplan templates have parameters `<dialect>Scale` and `<dialect>Offset` that are intended for this purpose.
This functionality is for instance needed when you want to do a sweep of the DC voltage of a Port instance. In Spectre the DC-voltage is multiplied by 2, while this is not the case in ADS or Hspice.

So to do a sweep of the DC voltage of a port instance your perl script could look like:

```perl
$P1 = dKitInstance->new('PORT', 'V1');
$P1->parameterValue('Vdc', 0.7);
$SWEEPPLAN = dKitAnalysis->new('SWEEPPLAN_LIN', 'Plan1');
$SWEEPPLAN->parameterValue('start', 0.5);
$SWEEPPLAN->parameterValue('stop', 1.5);
$SWEEPPLAN->parameterValue('numPts', 5);
$SWEEPPLAN->parameterValue('spectreScale', 0.5);
$SP = dKitAnalysis->new('SP', 'Sp');
$SP->parameterValue('device', 'V1');
$SP->parameterValue('parameter', 'Vdc');
$SP->addSweepPlan($SWEEPPLAN);
```

To get the original sweep values in the result file (see “Results Module” on page 4-33) you should also add to your script:

```perl
dKitResults->sweepVariableScale("V1.dc", "spectre", 2.0);
```

**Note**  The resultName of the parameter should be used to define the sweepvariable not the dKit Parameter name.

**Monte Carlo Analysis**

Monte Carlo analysis is similar to sweeping a parameter. Both require a main analysis such as DC, AC, Transient, or S-Parameter and both change one or more parameters during successive runs of the main analysis. The main difference is that the parameters are changed in a random manor rather than through a sweep plan.

The purpose of Monte Carlo Analysis in the Design Kit Model Verification tool is to verify that the design kit components and models for each simulator have the same parameters that can vary statistically, that the variation of these parameters is similar, and that the results of analysis with these variations are similar. Since Monte Carlo is varying the parameters randomly the results will not be exactly the
same, only similar. Because of this the judgment that the simulators are behaving
similar will have to be done visually.

Prior to performing a Monte Carlo analysis you should have completed the
non-statistical verification of each component or model. You should also have added
the statistical variations to the appropriate parameters in the netlists for each
simulator. It is expected that this has been done as there is no provision to add these
variations through the Perl scripts.

To create a Monte Carlo verification script you should have a main analysis such as
this AC analysis:

```perl
$SWEEPPLAN1 = dKitAnalysis->new(SWEEPPLAN_LIN, Plan1);
$SWEEPPLAN1->parameterValue(start, 1e8);
$SWEEPPLAN1->parameterValue(stop, 1e9);
$SWEEPPLAN1->parameterValue(numPts, 10);
$AC1 = dKitAnalysis->new(AC, AcSweep1);
$AC1->parameterValue(parameter, 'freq');
$AC1->addSweepPlan($SWEEPPLAN1);
```

You should then add a Monte Carlo analysis and make the AC analysis a sub analysis
to it as follows:

```perl
$MONTE = dKitAnalysis->new(MONTE, MSweep1);
$MONTE->parameterValue("iterations", "250");
$MONTE->parameterValue("variations", "process");
$MONTE->addSubAnalysis($AC1);
```

The number of Monte Carlo iterations is specified by the "iterations" parameter. The
"variations" parameter is specific to Spectre and is used to specify the type of
statistical variations to apply. Possible values for the "variations" parameter are
"process", "mismatch?", and "all". Then the Monte Carlo analysis should be added to
your circuit as follows:

```perl
$CIRCUIT->addAnalysis($MONTE);
```

Output Plans should also exist to save the results of any circuit results that you wish
to compare.
Viewing Monte Carlo Results

After running the Monte Carlo analysis, two types of information will be available,

- the parameters that are varying
- the varying output results from the circuit analysis.

To view the parameters you should use the measurement function histogram to see what values of the parameter fall into various data ranges. For more information on the histogram function, refer to the “Measurement Expressions” documentation. A typical example is shown here in Figure 4-1.

![Figure 4-1. Example measurement function histogram](image)

This was a parameter with a value of 210 and Gauss distribution with a 30% standard deviation. There are 500 iterations in the Monte Carlo analysis.
Building an Advanced Script

Figure 4-2 shows a plot of the output results of a Monte Carlo run. Notice the center line of the two traces are not the same. This difference would have previously been seen in verifying the parameter without statistical variations included. Notice that the statistical variations (width) of the two traces are very consistent. This shows that the statistical parameters are operating as expected.
Results Module

If the perl script you are using is not initialized using:

```
use dKitCircuit;
```

then add the following line before using any functions of the results module:

```
use dKitResults;
```

The results module (dKitResults.pm) contains functions to perform the following operations:

- “Set/Get the Offset of a Sweepvariable when Processing the Simulation Results” on page 4-34
- “Set/Get the Scale of a Sweepvariable when Processing the Simulation Results” on page 4-34
- “Reading the Simulation Results or Citifiles” on page 4-35
- “Retrieving a Handle to the Results” on page 4-35
- “Writing the Results to Citifiles” on page 4-35
- “Converting Citifiles to Datasets” on page 4-36
- “Comparing Two Simulator Results” on page 4-36
- “Performing a Simple Statistical Analysis” on page 4-37
- “Merging Citifiles into One Big Citifile” on page 4-37
- “Freeing the Memory taken by the Simulation Results” on page 4-37
Set/Get the Offset of a Sweepvariable when Processing the Simulation Results

To set the offset value used when the results module processes the data for a certain parameter use:

```perl
$offset = dKitResults->sweepVariableOffset('parameter', 'dialect', offsetValue);
```

Where:

- `'parameter'` is in the format `<deviceName>.<parameterName>`. <parameterName> should be the same as the `<resultName>` of the parameter defined using the Parameter Module. `parameter` is also the name found in the citi file containing the results.
- `'dialect'` designates the simulator results for which this offset should be applied.
- `offsetvalue` is the value of the offset. It normally equals `-sweepplanoffset`. `sweepplanoffset` is the offset applied to the sweeplan used to sweep this variable. See “Scale/Offset a Sweep Parameter” on page 4-28.

To get the offset value, use:

```perl
$offset = dKitResults->sweepVariableOffset('parameter', 'dialect');
```

Set/Get the Scale of a Sweepvariable when Processing the Simulation Results

To set the scale value used when the results module processes the data for a certain parameter use:

```perl
dKitResults->sweepVariableScale('parameter', 'dialect', scaleValue);
```

Where:

- `'parameter'` is in the format `<deviceName>.<parameterName>`. <parameterName> should be the same as the `<resultName>` of the parameter defined using the Parameter Module. `parameter` is also the name found in the citi file containing the results.
- `'dialect'` designates the simulator results for which this scale should be applied.
- `scalevalue` is the value of the scale. It normally equals `1.0/sweepplanscale`. `sweepplanscale` is the scale applied to the sweeplan used to sweep this variable. See “Scale/Offset a Sweep Parameter” on page 4-28.
To get the scale value, use:

```php
$scale = dKitResults->sweepVariableScale('parameter', 'dialect');
```

### Reading the Simulation Results or Citifiles

To read the results from a simulation or a CITI file, use the function:

```php
$Result = dKitResults->readData('<projectName>', '<dialect>');
```

Where `<projectName>` would normally be the circuitName of the simulated circuit. The supported dialects include the citi-dialect, as well as the supported simulators. In the case of the citi-dialect, the file `<projectName>.cti` is read and its content is stored in an item which can be accessed via the handle `$Result`.

**Note**  The design kit model verification tool is not able to read merged citifiles. For more information, refer to “Merging Citifiles into One Big Citifile” on page 4-37.

### Retrieving a Handle to the Results

When you have lost the handle to some result data, you can retrieve it using the function:

```php
$Result = dKitResults->getResults(<projectName>, <dialect>);
```

If the result data does not exist, this function will try to retrieve it using:

```php
dKitResults->readData
```

For more information, refer to “Reading the Simulation Results or Citifiles” on page 4-35.

### Writing the Results to Citifiles

To create a Citifile with the results use the function:

```php
$Result->writeCitifile('fileName', 'setName');
```

Where `fileName` is the name of the file to be created and the optional `setName` is the name of the set to be used when referencing it in the ADS data display server. For more information, refer to “Comparing Two Simulator Results” on page 4-36. It is advised to use `.cti` as the filename extension, and use the dialect as the `setName`. In
Building an Advanced Script

this case you are compliant with the rules used within the design kit model verification tool.

Converting Citifiles to Datasets

To convert a citifile to a dataset, use the function:

```c
    dKitResults->convertCitifile2Dataset('path2CitiFile', 'setName');
```

Where `path2CitiFile` is the location of the citifile and `setName` is the name to be used when referencing it in the ADS data display server.

**Note** The name of the citifile should end with `.cti` and `setName` should not be used if a merged citifile is given.

The name of the dataset will be the name of the citifile with all forward slashes (`/`) substituted by underscores (`_`), and the final `.cti` substituted by `.ds`.

For viewing the results with the ADS data display server, it is convenient if all data are located in one dataset. To do so, all citi data should be merged before the citifile is converted to a dataset. For more information, refer to “Merging Citifiles into One Big Citifile” on page 4-37.

Comparing Two Simulator Results

To calculate the difference between the results of two simulators, the following functions can be used:

```c
    $ReldiffHandle = dKitResults->compareDataRelative($Result1Handle, $Result2Handle);
    $AbsdiffHandle = dKitResults->compareDataAbsolute($Result1Handle, $Result2Handle);
```

Where `$Result1Handle` and `$Result2Handle` are the handles to result items (see “Retrieving a Handle to the Results” on page 4-35).

`$ReldiffHandle` will reference the relative differences between the simulation results and `$AbsdiffHandle` will reference the absolute differences. If you want to display these results using the ADS data display server, first transform the results to citifiles (see “Writing the Results to Citifiles” on page 4-35), then transform the citifiles to datasets (see “Converting Citifiles to Datasets” on page 4-36).
The result handles can also be used to obtain some simple statistical information (see “Performing a Simple Statistical Analysis” on page 4-37). Both simulation results ($Result1Handle and $Result2Handle) should have the same sweep variables, and only the differences between the matching dependent variables will be stored in the ReldiffHandle and/or AbsdiffHandle. Dependent variable names match if they have the same name (case sensitive).

Performing a Simple Statistical Analysis

To get the mean, maximum and minimum values of all dependent variables within a result item, use the command:

```php
$ResultHandle->calculateStatistics(['outputFileName']);
```

If 'outputFileName' is specified, the mean, maximum and minimum of all dependent variables will be written into the file 'outputFileName'. Otherwise, it will be written to the terminal window.

Merging Citifiles into One Big Citifile

To merge several citifiles into one citifile, use the command:

```php
dKitResults->mergeCitifiles('outputFileName', 'inputFileName1', 'inputFileName2', ...);
```

This is useful when you want to view the results using the ADS Data Display Server, because all data are available from within one dataset if this merged citifile is converted to a dataset.

**Note** The citifiles to be merged should all have different set names, otherwise the resulting dataset will be corrupt.

Freeing the Memory taken by the Simulation Results

To free the memory taken by previously run simulations, issue the command:

```php
dKitResults->freeMemory('circuitName' [, 'dialect']);
```

where circuitName is the name of the circuit and dialect is the name of the simulator dialect. If no dialect is specified, all results for circuitName will be deleted.
Building an Advanced Script

Design Kit Model Verification Tool Perl Modules

The following sections contain a summary of the design kit model verification tool Perl Module (*.pm) files that contain the functions used for creating your individual perl scripts. The tables provided can be used as a quick reference when developing your scripts. The following information is provided for each of the functions listed:

- Function name
- Function description
- Function syntax
- Variable definitions (i.e. variables listed in angled brackets < .. >)
- Function limitations
- References to examples
Template Module (dKitTemplate.pm)

The dKitTemplate.pm file contains the functions used for creating the design kit model verification template script.

Table 4-3. dKitTemplate.pm Functions Summary

<table>
<thead>
<tr>
<th>Function</th>

<tr>
<td>addAnalysis()</td>
<td>Adds an analysis. $CircuitHandle-&gt;addAnalysis($Analysis);</td>
</tr>
<tr>
<td>addInstance()</td>
<td>Adds a component. $CircuitHandle-&gt;addInstance($Instance);</td>
</tr>
<tr>
<td>addModelLibrary()</td>
<td>Adds the path to a modelLibrary. $CircuitHandle-&gt;addModelLibrary($MODELLIBRARY);</td>
</tr>
<tr>
<td>addParameter()</td>
<td>Adds a parameter to a subcircuit. $CircuitHandle-&gt;addParameter(&quot;&lt;parameterName&gt;&quot;);</td>
</tr>
<tr>
<td>addSimulatorOption()</td>
<td>Adds simulator options. $CircuitHandle-&gt;addSimulatorOption($OPTION);</td>
</tr>
<tr>
<td>addToSubcircuits()</td>
<td>Catalog circuit as a subcircuit for subsequent use. $CircuitHandle-&gt;addToSubcircuits([nodeList, parameterList [optionalParameterList]]); Where: nodeList = The list of node names (e.g. ['n1', 'n2', ...]). requiredParameterList = A list with the required parameters and their initial values (e.g. ['l=1e-3', 'w']). optionalParameterList = A list with the optional parameters and their initial values (e.g. []).</td>
</tr>
<tr>
<td>circuitName()</td>
<td>Defines a circuit name. $CircuitHandle-&gt;circuitName(&quot;&lt;circuitName&gt;&quot;);</td>
</tr>
<tr>
<td>clone()</td>
<td>Create a new circuit based on a subcircuit. $CircuitHandle = dKitCircuit-&gt;clone(&quot;subcircuitName&quot;);</td>
</tr>
<tr>
<td>createSubcircuitDatabaseFile</td>
<td>Store all currently defined subcircuits in the database file. $Circuit-&gt;createSubcircuitDatabaseFile;</td>
</tr>
</tbody>
</table>
createSubcircuitTemplateOnly()  
Define a template for a subcircuit only containing instances.

$CircuitHandle->createSubcircuitTemplateOnly("<templateName>", nodeList, requiredParameterList, optionalParameterList);

Where:
- <templateName> = The name of the template.
- nodeList = The list of node names (e.g. ['n1', 'n2', ...]).
- requiredParameterList = A list with the required parameters and their initial values (e.g. ['l=1e-3', 'w']).
- optionalParameterList = A list with the optional parameters and their initial values (e.g. []).

createTemplateANDaddTocircuits()  
Catalog circuit as a subcircuit and define a template.

$CircuitHandle->createTemplateANDaddTocircuits("<templateName>", nodeList, requiredParameterList, optionalParameterList);

Where:
- <templateName> = The name of the template.
- nodeList = The list of node names (e.g. ['n1', 'n2', ...]).
- requiredParameterList = A list with the required parameters and their initial values (e.g. ['l=1e-3', 'w']).
- optionalParameterList = A list with the optional parameters and their initial values (e.g. []).

debug()  
The module debug facility can be used for all modules. Level 0 turns debugging off. The higher the value of level, the more information you receive. The highest level value is currently 100; however, some intermediate values are not used.

dKitCircuit->debug(<level>);

dKitCircuit  
Initialize all modules.

use dKitCircuit;

deleteResultsFromMemory()  
The deleteResultsFromMemory() function releases memory taken by the simulation results of the circuit.

$CircuitHandle->deleteResultsFromMemory

getAnalyses  
Get a list with all of the analyses within a circuit.

my @Analyses = $CircuitHandle->getAnalyses;

Example Device Test Scripts

The example scripts shown in this section are for reference only. In order to use these scripts, the appropriate model files need to be provided. This involves making changes to the `diode_test_dc.pl` script to reference the required model files and to designate the correct sections. The `create_diode.pl` script may also need to be changed to reflect the correct instance line definition for the associated models.

`diode_test_dc.pl`

The `diode_test_dc.pl` script is a simulation to compare ADS vs. Hspice using the design kit model verification tool. It is a simple diode in parallel with a DC voltage source. The only variable swept is the forward diode voltage, $V_d$. The output is intended to be Capacitance and Current vs. $V_d$.

Note: There are required perl scripts, `diode_create.pl` and `diode_parameters.pl` that must be executed before this script. This is so that a model with required parameters can be created for a diode. The `diode_create.pl` and `diode_parameters.pl` scripts only need to be executed once. For more details, refer to the contents of “`diode_create.pl`” on page 4-54 and “`diode_parameter.pl`” on page 4-56.

This test is written for the forward region ($V_{dc} = 0$ to 0.7) for the ndiode and pdiode diodes.

```perl
#!/usr/bin/perl
BEGIN {
    if ($ENV{DKITVERIFICATION} eq "") {
        if ($ENV{HPEESOF_DIR} eq "") {
            print "Please set environment variable DKITVERIFICATION
to point to the design kit
verification installation directory

        exit 1;
    } else {
        $ENV{DKITVERIFICATION} = "$ENV{HPEESOF_DIR}/design_kit/verification";
        }
    } else {
        $ENV{DKITVERIFICATION} = "$ENV{HPEESOF_DIR}/design_kit/verification";
    }
    $myLibPath = "$ENV{DKITVERIFICATION}/perl/lib";
    if ( ! -d $myLibPath) {
        if ( $ENV{DKITVERIFICATION} eq "$ENV{HPEESOF_DIR}/design_kit/verification"})
        {
            if ( ! -d "$ENV{HPEESOF_DIR}/design_kit/verification")
            {
```

# Build the circuit
$testName = "test_diode_dc";  # Change this circuit name depending upon which
# model you are testing.

Example Device Test Scripts 4-53
Building an Advanced Script

```perl
$CIRCUIT = dKitCircuit->new($testName);
$CIRCUIT->addSimulatorOption($OPTION1);
$CIRCUIT->addModelLibrary($MODLIB);
$CIRCUIT->addAnalysis($TempSweep);
$CIRCUIT->addInstance($D1);
$CIRCUIT->addInstance($vd);

@device = ("ndiode", "pdiode");
for $device (@device) {
    $testName = "test_" . $device . "_dc";
    $CIRCUIT->circuitName($testName);
    $D1->parameterValue('model', $device);
    $CIRCUIT->simulate('ads', 'hspice', 'spectre');

    ### calculate statistics ...
    $adsDataP = dKitResults->getResults($CIRCUIT->circuitName, "ads");
    $spectreDataP = dKitResults->getResults($CIRCUIT->circuitName, "spectre");
    $hspiceDataP = dKitResults->getResults($CIRCUIT->circuitName, "hspice");
    $diff = dKitResults->compareDataRelative($adsDataP, $spectreDataP);
    $diff->writeCitifile("$CIRCUIT->circuitName" . "_asdiff.cti", "diffAdsSpectre");
    print $diff->calculateStatistics("$CIRCUIT->circuitName" . "_asstat.dat" nga);
    $diff = dKitResults->compareDataRelative($adsDataP, $hspiceDataP);
    $diff->writeCitifile("$CIRCUIT->circuitName" . "_ahdiff.cti", "diffAdsHspice");
    print $diff->calculateStatistics("$CIRCUIT->circuitName" . "_ahstat.dat");
    $diff = dKitResults->compareDataRelative($hspiceDataP, $spectreDataP);
    $diff->writeCitifile("$CIRCUIT->circuitName" . "_hsdiff.cti", "diffHspiceSpectre");
    print $diff->calculateStatistics("$CIRCUIT->circuitName" . "_hsstat.dat");
}
```

diode_create.pl

The diode_create.pl script will create a two port network that will represent the diode used in the diode simulations. This script must be executed before any of the other diode scripts are ran. It is only required to be executed once. Once the script is executed, it will append dKitTemplate.pm to the template file. This is the required template for the diode.

```perl
#!/usr/bin/perl
BEGIN {
    if ($ENV{DKITVERIFICATION} eq "") {

Building an Advanced Script
Chapter 5: Comparing Simulation Results

This chapter describes the steps for comparing simulation results between the different simulators.

Viewing Your Results in a Data Display

Simulation results are stored in datasets (*.ds) and citifiles (*.cti). To view your results in an ADS Data Display:

1. Launch ADS and create a new project `<adsproject>` if necessary.
2. Copy all of your datasets to your ADS project’s data directory (`<adsproject>/data`).
3. Launch the ADS Data Display server from your ADS window. From the ADS Main window, choose Window > New Data Display.
4. Create a template to view your results. For more information, refer to “Using a Template in Your Display” in the ADS “Data Display” documentation.
5. Select the dataset to view the results. If your parameters have been defined correctly, you should be able to use the `<dataset><simulator><parameter>` to access the different results for the different simulators, with `<simulator>` equal to ads_sim, spectre_sim or hspice_sim.

For more information on datasets (*.ds) and citifiles (*.cti), refer to Chapter 7 of the ADS "Circuit Simulation" manual.

Script Based Comparisons

The design kit model verification tool also contains some functionality to do script based comparisons of the simulation data. The following operations are needed:

- “Retrieving a Handle to the Results” on page 4-35
- “Comparing Two Simulator Results” on page 4-36
- “Performing a Simple Statistical Analysis” on page 4-37

If you want to do the comparison from within a different script other than the one used to run the simulation, the circuit debug level needs to be set to 1 (see debug facility of “Circuit Module (dKitCircuit.pm)” on page 4-42), in order not to delete the usable simulation results upon completion.
Comparing Simulation Results

If you want to save the comparison results or view them using the ADS Data Display server, the functionality described in the following sections is also needed.

- “Writing the Results to Citifiles” on page 4-35
- “Converting Citifiles to Datasets” on page 4-36

For a description of these functions, refer to “Results Module (dKitResults.pm)” on page 4-49.

Example Script

This script is used to compare the simulation results between Spectre, Hspice and ADS for a circuit called test_diode.

The script starts as usual with the default header. When running this script, three sets of data will be created with the differences between the output data of two simulators: the point-to-point relative difference will be put in a citifile, and the statistics of these differences are saved in text files.
#!/usr/bin/perl

BEGIN {
    if (!defined($ENV{DKITVERIFICATION})) {
        if (!defined($ENV{HPEESOF_DIR})) {
            print "Please set environment variable DKITVERIFICATION to point to the design kit verification installation directory
        exit 1;
        } else {
            $ENV{DKITVERIFICATION} = "$ENV{HPEESOF_DIR}/design_kit/verification";

    $diff->writeCitifile("$testName" . "_asdiff.cti", "diffAdsSpectre");
    print $diff->calculateStatistics("$testName" . "_asstat.dat");
Comparing Simulation Results

$diff = dKitResults->compareDataRelative($adsDataP, $hspiceDataP);
$diff->writeCitifile("$testName" . "_ahdiff.cti", "diffAdsHspice");
print $diff->calculateStatistics("$testName" . "_ahstat.dat");

$diff = dKitResults->compareDataRelative($hspiceDataP, $spectreDataP);
$diff->writeCitifile("$testName" . "_hsdiff.cti", "diffHspiceSpectre");
print $diff->calculateStatistics("$testName" . "_hsstat.dat");
Chapter 6: Documenting Your Simulation Results

This chapter describes the fundamentals of using the ADS Electronic Notebook.

Creating Verification Documentation

The ADS Electronic Notebook enables you to create HTML documents using the designs and results within a project. The operations and features provided within the notebook enables you to:

- Automatically capture and update images from ADS schematics, layouts and data displays.
- Produce HTML formatted output of results which can be distributed easily without the necessity of ADS.
- Exercise the ability to import graphic images from external sources. This enables you to add documentation from other products.

To access the ADS Electronic Notebook Editor:

1. Choose **Tools > Electronic Notebook**. The ADS Electronic Notebook Editor appears.
2. Enter the Notebook Title, Engineer, Company and Copyright information in the Notebook Properties section of the dialog.

---

**Note** You can return to and edit the Notebook Properties section of the dialog at any time by clicking the Notebook Properties button below the Page Operations section of the dialog.

---

3. Use the Browse button to select an existing Banner Image to be displayed at the top of your document. Click the View button to preview the image.
Adding a Page

The Electronic Notebook supports a variety of page types. Generally, a page consists of a beginning text area, an image and a bottom text area. The text area is HTML formatted. This means that the text in this area may make use of any of the standard HTML formatting commands. To add a new page:

1. Click the Add Page button. The New Notebook Page dialog box appears.

2. Select the appropriate Page Type from the list of options. For more information, refer to “Page Types” on page 6-2.

3. Click OK to continue or Cancel to abort the operation. If you clicked OK, the page is inserted below the currently selected page. It is not inserted into the selected page's folder. If this is desired, use the right arrow operation after the page is inserted.

Page Types

• **Folders**  There are no explicit folder pages in the notebook. Any page can become a folder. This is accomplished by moving a page beneath the desired folder page and moving it to the right by using the right arrow button. Similarly, moving a page to the left takes it out of its folder.

• **Description**  This places a blank page into the notebook. This page has only one text area. It is recommended that general descriptions of topic areas be placed on these pages.

• **Schematic**  This places a schematic image on the page and has the standard two text areas.

• **Layout**  This places a layout image on the page and has the standard two text areas.

• **Data Display**  This places a data display image on the page and has the standard two text areas.

• **Image**  This places an external image on the page and has the standard two text areas. The image can be a jpeg, gif, bmp or xwd image. The image is automatically converted to jpeg format during page generation so that complete portability is possible.
Notebook Operations

- **Save**  Saves the current notebook data. The HTML data is not created when this data is saved.
- **Generate**  Saves the current notebook data. The HTML data is then created and a web browser is opened up to view the resulting notebook.
- **View**  Opens the current HTML notebook in a browser window. This command does not save the current configuration or generate new HTML data.
- **Zip HTML**  Saves the current notebook HTML data in a zip file. A prompt appears requesting the location of the zip file.
- **Quick Help**  Displays the on line help.
- **Cancel**  Exits the ADS Electronic Notebook.

Page Operations

Page operations affect the order of the pages within the notebook. The notebook is based on a hierarchical structure. Each page can become a folder simply by having another page underneath it.

Page Movement

The following operations move the pages around within the notebook.

- **Up Arrow**  Moves the selected page up. If the selected page is at the top of a list, it will be unable to move.
- **Down Arrow**  Moves the selected page down. If the selected page is at the bottom of a list, it will be unable to move.
- **Left Arrow**  Moves the selected page left. This will move the page out of the current list it's in and into the one above it. If the page is at the top level, it will be unable to move.
- **Right Arrow**  Moves the selected page right. This moves the current page into the hierarchy of the page above it. If the page is already within the hierarchy of the preceding page, it will be unable to move.
Page Creation and Deletion

- **Add Page**  This operation brings up a dialog which allows the addition of any of the default page types. The page is inserted below the currently selected page. It is not inserted into the selected page's folder. If this is desired, use the right arrow operation after the page is inserted.

- **Delete Page**  This operation brings up a dialog confirming the deletion of the selected page. If a page has pages underneath it, a special dialog will confirm the deletion of the page and all its children.

Notebook Generation

Notebook generation consists of two parts, the HTML file creation and the image capture. The HTML generation for the notebook is done automatically whenever the notebook is generated using the Generate command.

The Save command does not generate the HTML, it only saves the notebook data, so that when the notebook is restarted it can be resumed from its last state.

The images which are used in the notebook are image captures taken directly from the screen. During this process, the notebook is iconized so that it will not get in the way of the image capture process. After all the images have been captured, it is maximized back to its last size. It is important to remember that this process is a direct screen capture and any windows placed on top of an ADS window during this process will be captured instead of the desired ADS image.

During the image capture process, each desired design or data display is opened and then resized appropriately for correct screen capture. Again, these designs do not open any faster than they normally would, so patience is required for large schematics and data display files.

During the image capture process, only those designs and data displays which have changed since the last image capture are captured. However, if the image should not be updated automatically, the check box on the desired page, **Update Images Automatically**, should be unchecked. If this box is unchecked, the image will not be recaptured when the design or data is updated.
Appendix A: Template List

This appendix contains a list of default templates currently available in the standard list of templates.

The following sections contain the currently defined default templates:

- “Analysis Templates” on page A-2
- “Outputplan Templates” on page A-5
- “Sweepplan Templates” on page A-7
- “Simulator Options Templates” on page A-9
- “ModelLibrary Template” on page A-10
- “Components/Instance Templates” on page A-11
- “Circuit Initialization” on page A-30

Note: In each of the tables listed in this appendix, the parenthesis containing the specific simulators (<simulator>) indicates that the parameter is available in that particular simulator.
Analysis Templates

This section contains the default analysis templates.

The “parameter” for all of the analysis templates defines the simulation or device parameter to be swept. If that parameter is part of a device, device should be set to the name of the instance defining the device. For more information on adding a sweep plan and output plans, refer to “Adding a Sweepplan” on page 4-26 and “Adding an OutputPlan” on page 4-27.

A-4
Outputplan Templates

This section contains the default outputplan templates.

ADS does not support OUTPUTPLAN_CURRENTS, and OUTPUTPLAN_DOPS will give all parameters for all devices if at least one parameter of one device is given. Outputplans added to S-parameter analyses will be ignored.

Outputplan for Device Currents

Table A-7. Outputplan for Device Currents Template

<td></td>
</tr>
<tr>
<td>nodes</td>
<td>(ads) (hspice) (spectre)</td>
</tr>
</tbody>
</table>
Sweepplan Templates

This section contains the default sweepplan templates. It is possible to add an offset or scale the values of the sweepplan for a specific simulator using the <dialect>Scale and <dialect>Offset parameters. To re-normalize the values in the results, the functions dKitResults->sweepVariableScale and dKitResults->sweepVariableOffset can be used.

Linear Sweep Plan

Table A-10. Linear Sweep Plan Template

<table>
<thead>
<tr>

<td>(hspice)</td>
<td>(hspice)</td>
<td>(ads)</td>
<td>(ads)</td>
<td>(spectre)</td>
<td>(spectre)</td>
</tr>
</tbody>
</table>
Simulator Options Templates

This section contains the default simulator options templates.

Circuit Simulator Options

For each simulator, the options should be specified as a list using a space delimited string as they need to be specified for the simulator. For example:

```php
$myOption->parameterValue('hspiceOptions', "nopage acct=0 dcap=1 numdgt=10");
```

<table>
<thead>
<tr>
<th>TemplateName:</th>
<th>SIMULATOROPTION</th>
</tr>

<td>adsOptions</td>
<td>(ads)</td>
</tr>
<tr>
<td>hspiceOptions</td>
<td>(hspice)</td>
</tr>
<tr>
<td>spectreOption</td>
<td>(spectre)</td>
</tr>
</tbody>
</table>

Circuit Temperature

<table>
<thead>
<tr>
<th>TemplateName:</th>
<th>TEMPERATURE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>Circuit Temperature</td>
</tr>
<tr>
<td>Parameters:</td>
<td></td>
</tr>
<tr>
<td>temperature</td>
<td>(ads)</td>
</tr>
<tr>
<td></td>
<td>(hspice)</td>
</tr>
<tr>
<td></td>
<td>(spectre)</td>
</tr>
</tbody>
</table>
ModelLibrary Template

This section contains the default model library templates.

Model Library

ModelLibrary should contain the path to the library, SectionName is the section of that library to be activated, if it is omitted the whole library is included.

Table A-14. Model Library Template

<table>
<thead>
<tr>
<th>TemplateName:</th>
<th>MODELLIBRARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>Includes one modellibrary.</td>

<td>(hspice)</td>
</tr>
<tr>
<td>spectreModelLibrary</td>
<td>(spectre)</td>
</tr>
<tr>
<td>spectreSectionName</td>
<td>(spectre)</td>
</tr>
</tbody>
</table>
Components/Instance Templates

This section contains a description of the default instance templates to be added to the circuit using the addInstance function from the Circuit module.

Parameter

This template defines a circuit parameter. value can be a numerical value (single parameter) or an equation. Be sure to add all single parameters to the circuit before adding equation parameters, otherwise the simulation results can be very awkward.

Table A-15. Parameter Template

<table>
<thead>
<tr>
